I have had them open..and there isn't much you would be able to do unless there was just a bad connection.

I would:

1. be certain the input frequency is properly centered.
2. be sure the switch is clean and functioning properly
3. swap in the filter inputs and outputs either at the switch or on the filter bodies to see if the same filter remains bad in the new switch position. If the freq is centered, the switch is functioning and all other circuits are common, then if it behaves differently, it might not be bad.

4289. Need replacement for .82 ohm resistor in Drake L4B power supply

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-09-05 21:44:49 UTC
From: K4GM- George
Topic: 4289 Message: 4289

I have an "ailing" R12 in my L4-B power supply. Although functioning a portion of the outer cover has split off and I am afraid it is only a matter of time until it fails. The resistor is listed as .82 ohms at 2 watts. There is a note to "replace with IRC Type BWH resistor only". I did find a replacement at R&J Electronics but the smallest quantity is a package of 18!! Does anyone know where I might locate a good substitute? Is this something I could find at Mouser if I call. Can't seem to find online at Mouser but may not be using right search criteria.

George,

Try Harbach Electronics.
http://www.harbachelectronics.com/main/page_products_drake_l4l4bl7.html

Also, I don't see why you can't substitute a metal oxide or carbon film resistor of the same rating. Maybe someone on the reflector can elaborate.

I purchased several from Harbach for my L7 several months ago. It's best to stay with the resistors that are designed to act as fuses - something about failure times and flames.

Jim -

The 'original' was a wirewound. It was chosen to 'disintegrate' in case
of a short circuit, as in a tube short or other nasty.

Metal oxide might work, but will probably survive long enough to become
red hot before it 'melts' or ....

Carbon film wouldn't survive the normal surge currents of operation.

Thanks Garey,

No, no 4 series yet, but with all the good things I hear about them, I'm confident that'll be my next HF addition to the shack!

#1815 it is then.

73!

Sort of off topic, but:

I checked the S meter in my new TR-4C project unit, and it is just about dead-nuts on at 6 dBm per S unit! It works -very- well!

4309. Drake UV-3 Pictures

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-09-07 23:31:13 UTC
From: k2wh_bill
Topic: 4309 Message: 4309

I just uploaded a group of high resolution images of the Drake UV-3 VHF/UHF transceiver. The darth of information about this rig prompted me to put them here. In the images you can see (via the side view), how the 220 and 440 modules are assembled to the back of the basic 2 meter section basically extending the lenght of the UV-3 backwards.

Believe it or not, I salvaged this UV-3 from the scrap bin. Someone tossed it in the garbage. The 440 receiver works, volume, squelch work, but 220 and 144 no action. I have not tried to transmit with it. Obviously it needs some work but the inside (I removed the cover for the picture) is immaculate. So, I guess I'll hang onto it and sometime in the future get into testing it thoroughly.

Enjoy the images. They may be the best ones out there.

Brenton -

I probably should clarify my earlier post re. the S-Meter lamp.

The 'official' bulb for the TR-7 is the #53, which is a round, bayonet based lamp.

I like the #1815, a tubular, bayonet base, for the S-Meter as it makes the meter a little brighter
and easier to read.

The #1815 runs a little hotter, and you need to be careful to place it well away from the meter.
You do NOT want to use the #1815 for the PTO, as it ends up too close to the dial... Not good.

The 'other' advantage is that the #1815 is rated for three times the life of the #53.

All that said, the #53 is probably easier to find locally.

Hi Garey,

Thanks for this follow up. I tried Radio Shock, and came up empty, so it's off to my favorite electronics supply hut across town today for a travelling lunch.

I like your suggestion to go with the brighter bulb, though with caution about its deployment. If I can get both bulbs, I'll do that, in the event that the 1815 gives me reason to worry once I get my fingers in the rig.

Boy, you really dont' realize how dependent you are on that S meter until you can't read it!

Thanks "Gaz".

4312. Drake T-4XB acc crystal socket use question

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-09-09 12:12:37 UTC
From: w4mjr
Topic: 4312 Message: 4312

I have a question for Drake T-4XB owners. My transmitter has been in use daily for about a year now and works great on all bands. I have just bought crystals for the acc socket position. 160, 17, 12 and 10 meters. My new bands all work fine except 160 meters. Only 2 watts there. All knob settings are in correct position and I can even tune enough to monitor my signal and spot. This might be the first time the T-4XB has ever had crystals in the in the acc socket. Could there be a internal adjustment before use for 160 meters that I am not aware of.
Thanks,
Mike W4MJR

Les -

Well we started out talking about bulbs for the TR-7 S-Meter. I first mentioned the #47 because I thought we were talking about the 4 Series, and it went downhill from there! :-)

Once it was determined that the initial query was about the TR-7, I suggested the #1815 because that's what I use. It's brighter than the original #53, but you have to be careful because it's also hotter.

I later clarified that the original was the #53, and that's when Jim piped up with the "LEDs are brighter and better" line, or something to that effect, to which I replied "Yuk!" :-)

While it's true that the LEDs ARE brighter and better, this ol' Luddite has been looking at that pretty "Lee Lighting #172 film with #755 bulb" for too long.!! (1965) Anything else just "ain't Drake". I just threw in another number there, the #755 is a bulb like the #47 that has about 6+ times the life expectancy of the #47. I've been using them since about 1970, and haven't had to replace one yet! (20,000 hours, as opposed to 3,000 for the #47)

So as is usually the case around here, much "... sound and fury, signifying nothing"! :-)

From: Garey Barrell
Topic: 4312 Message: 4325

Mike -

The 160M band is at the VERY BOTTOM of the range of the circuits in the T-4XB. First off, it will NOT go below 1.8 MHz, or at least not very far. So if you are tuning up on say 40M at 7.050 MHz and switch to 160M you'll be at 1.550 MHz and zilch!

First, if you haven't already, crank the PTO up to 300 or better and try again. If still low power, you may need to adjust the trim caps on the side of the chassis for the 1.8 - 3.0 MHz band. Note here that they do SAY "1.8 - 3.0 MHz! If you do, be SURE to use an insulated alignment tool. For your protection, the trimmers have +250 VDC on them, _AND_ if you short one to the chassis, even momentarily, you will damage a resistor in the transmitter.

If this doesn't resolve your problem, let us know!

> I have a question for Drake T-4XB owners. My transmitter has been in use daily for about a year now and works great on all bands. I have just bought crystals for the acc socket position. 160, 17, 12 and 10 meters. My new bands all work fine except 160 meters. Only 2 watts there. All knob settings are in correct position and I can even tune enough to monitor my signal and spot. This might be the first time the T-4XB has ever had crystals in the in the acc socket. Could there be a internal adjustment before use for 160 meters that I am not aware of.

Les -

Well we started out talking about bulbs for the TR-7 S-Meter. I first mentioned the #47 because I thought we were talking about the 4 Series, and it went downhill from there! :-)

Once it was determined that the initial query was about the TR-7, I suggested the #1815 because that's what I use. It's brighter than the original #53, but you have to be careful because it's also hotter.

I later clarified that the original was the #53, and that's when Jim piped up with the "LEDs are brighter and better" line, or something to that effect, to which I replied "Yuk!" :-)

While it's true that the LEDs ARE brighter and better, this ol' Luddite has been looking at that pretty "Lee Lighting #172 film with #755 bulb" for too long.!! (1965) Anything else just "ain't Drake". I just threw in another number there, the #755 is a bulb like the #47 that has about 6+ times the life expectancy of the #47. I've been using them since about 1970, and haven't had to replace one yet! (20,000 hours, as opposed to 3,000 for the #47)

So as is usually the case around here, much "... sound and fury, signifying nothing"! :-)

Actually, I agree with Gary WRT the 4-line and other older gear. But there is something about the monchromatic "ice blue" look of the LEDs that just seems to click with the more modern styling of the 7-line IMO.

Joachim -

You need to pick up the Premixer signal, and then subtract 5.645 MHz
from that. Your counter has to be able to have a programmed 'offset'
capability to do this.

The pick-off points for the TA-4, which provides an 'INJection' jack to
allow transceive operation with the T-4X(any) transmitters, would be the
best place to find where to connect.

I've attached information on the TA-4.

4340. Chassis mount capacitor trimmers on TR-4C

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-09-14 12:54:43 UTC
From: w1kilofoxtrot
Topic: 4340 Message: 4340

I've found that the previous owner evidently soaked the TR-4C in some kind of solvent. All of the switch decks were soaked, but are now clean, dry-er and working.
But the carrier frequency cap, C130; and the calibrator trim cap, C45, have nowhere near the adjustment range I think they should. I've seen some discussions about dismantling them, and cleaning them up, but I wonder if anyone here has actually done so?
Frankly, I'm worried about keeping tabs on the little retaining clip, and I've not seen many of these components available through the usual channels.
Any thoughts, words of wisdom, etc?

73,
Steve

From: Garey Barrell
Topic: 993 Message: 4341

Here is the information that Drake left out of their manuals!

Unique supplemental service information CDs available for the Drake TR-4, TR-4C/Cw/CwRIT, B and C
Lines and the 2-B receiver.

High resolution color photos of the under chassis and individual PC boards of each unit, with all
parts identified and keyed to a parts list make it easy to locate any component. No more trying to
trace wires through bundles, etc. This information is not available elsewhere and really makes a
difference in servicing these units.

These CDs are NOT just scans of the original manuals that were included with the equipment when new.
High resolution scans of the original manuals ARE on the CDs, along with scans of manuals for
associated equipment such as the C-4, FS-4, MN2000, L-4B, W-4, etc.

Samples of these pages (at reduced resolution) and purchase information are at <www.k4oah.com>.

All,

My MS4 speaker on my B-Line has been sounding very tinny over the past year and I needed to turn up the AF gain to around 2 o'clock to get a reasonable listening level. I decided to order one of the replacement's from Surplus Sales and just installed it tonight. I must say the difference is significant (at least to my ears).

Also, The new speaker is much heavier and also has a bigger magnet compared to the stock speaker (10 O'clock setting gives me a decent listening level now).

The hardest part about the installation was removing the old speaker. The screws and nuts that secure the speaker to the front grill were a pain to get off. The compound that Drake used to keep the nuts locked down must have been the predecessor to Locktite Red.

Well, its too late now but in the future sometimes you
can loosen up the lacquer by heating with the tip of a
soldering iron.
"Tinny" sounds like perhaps a rubbing voice coil. While
this sometimes results in a scratchy sound if its warped
enough to be wedged in the gap it may not be able to move
enough. You can tell by pushing on the cone gently with your
finger or put a single flashlight battery across the voice
coil, it should move the cone in or out quite visibly. If
its rubbing this will show it up. Rubbing can also be caused
by particles stuck in the gap. Sometimes you can get them
out by sliding waxed paper around in the gap. Magnetic
particles can sometimes be removed with Scotch tape but its
hard to keep it from sticking to the pole piece or voice
coil, and, its usually not possible to get into the outside
of the gap.
Magnet weight does not always mean a more powerful

magnet, it depends on the material its made of. Small sized Alnico 5 magnets will, for instance, have a higher gap flux density than a much larger ceramic magnet.

hard to keep it from sticking to the pole piece or voice
coil, and, its usually not possible to get into the outside
of the gap.
Magnet weight does not always mean a more powerful
magnet, it depends on the material its made of. Small sized
Alnico 5 magnets will, for instance, have a higher gap flux
density than a much larger ceramic magnet.

Bob -

TP-3 is at the bottom edge of the board, but there is a jumper wire from the test point to a pad near the top edge of the board.

There is a drawing of the board on page 24 of the manual showing the test point and 'Point A' with the jumper as a black, straight line between them. IF you have flea clip or other small clip lead, you can access the point on the IC lead that is one lead down towards the center of the board from the top lead. The IC pins on either side are ground, so be careful that you don't short to them.

Garey,
Ah-hah, thanks.
I did the step 6.4.2, thanks to your help. I ended up touching it up with an accurate frequency counter after looking over the circuit. Just held a scope probe insulated tip near the T11 wiring and adjusted T11. I guess using a freq counter was not an easy option in 1968.
I picked up a cheap somewhat abused t-4xb, I might have to buy one of your CDs to get me through that one.

From: qrpcwop
Topic: 4333 Message: 4352

Update:

The speaker, a first-rate Misco component, arrived on Friday, I popped it in on Saturday. My R8 and TR-7 sound absolutely magnificent.

Actually, the speaker in the cabinet wasn't original - it was the no-longer-available Radio Shack unit. Nonetheless, it was well worth the expenditure.

4353. Drake 34PNB noise blanker alternative

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-09-21 14:53:18 UTC
From: billykatzz
Topic: 4353 Message: 4353

When you can find them (RadioMart has an auction on Ebay currently) those 34PNB noise blankers are pretty darn pricey.

Does anyone have personal experience either homebrewing a version of the unit or jury-rigging an alternative? I keep looking at the knob on the lower right of my TR-4Cw and thinking that I may be missing something.

The Tr-4Cw was offered as a mobile rig. The noise blanker was (marginally) useful there as vehicles were very noisy - ignition. For home use, the blanker was very rarely used. Today with electronic ignitions, the spark noise is essentially gone and there are no points/distributor where a lot of noise was generated.

From: Paul Pollock
Topic: 4353 Message: 4355

Hi Steve AI0W,

I have found, from personal experience, some very interesting data. I run a Yaesu mobile in my 99 Chevy Blazer, and it is known to be relatively clean, with hi-performance shielded spark wires and a new alternator to kill whine. Car has good grounds thru-out.
However, while there never is ignition noise or whine on the car stereo, the noise blanker in the Yaesu-857d is squashing an S-8 ignition level. That is normal, even on new cars (they vary some, but the ignition noise is present in virtually all cars). I've owned used, and I've owned new, and all have had some ignition noise (varying from S-5 to 10-over).

As for the blanker in my TR-4, it has proved useful at times. I very often, in my local, get significant racket on 80 and 40; and I can often take a S-5 down to a S-2 using my noise blanker. Noise on the higher bands is usually lower, and the blanker is less necessary, but I would not own a radio that had no Blanker. I'm very glad my Drake has one.
As an aside, before I put my TR-4 on the air (after purchase some months ago), I sent the radio to Jeff Covelli, and he refurbished the radio, and aligned it. The noise blanker also needed attention as it too was out of alignment. He says it is a good blanker, when it is working right and aligned per the manual.

Have fun and good luck!

4356. Re: Seeking TR-4C upper sideband crystal filter

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-09-22 21:24:55 UTC
From: w1kilofoxtrot
Topic: 4277 Message: 4356

Finally got back to this. Decided to short out the filters, and things are working much better. There was very little coupling in the 'X' filter, so could not get any output from the rig until I shorted it out. Dummy load is nice and warm, now! Receive is not bad either, but of course I need the filter to knock out the opposite sideband, so this is a test-only proposition.

It does mean I need a new filter, though. Anyone parting out a TR-4 rig? Or, should I simply use some KVG filters, available from a vendor in Israel? I think the KVG are 8 pole, high quality units, but I'd have to fabricate a new bracket for them. I'd rather keep it original, if I can.

one more recommendation for the Misco speaker. the only unfortunate aspect of the purchase was the $12 shipping charge. for communications I think the response is perfect. some might like more bass for AM, wideband SSB, etc. I had previously tried to save some money and purchased a Boss 10oz 4 ohm speaker from Amazon. it would not fit without cutting metal, and the inefficiency was too much for the Drake output stage. that is to say, it sounded feeble and muddy.

it appears that this new surplus speaker is the perfect replacement, albeit an expensive one.

I did the same, same result. I had no real trouble removing the
original speaker. One thing yet to be seen is if it leaves room for an
AC-4 since it is thicker than the original.

Bob,

The replacement speaker matches the footprint of the original speaker (5”x7”). So no, it will not fit in the MS7 cabinet.

From: bpierfel
Topic: 4363 Message: 4363

My transmitters PTO dial was apparently exposed to sunlight for ? years and is brown (not from smoking) where the dial was parked.
Anyone have a junker dial available or know of a repro? It appears to be the same dial as my R-4B has.
tnx
Bob KB8TL

4364. R-4B problem

I picked up a R-4B at the Ten Tec Hamfest last weekend. Plays good but every so often the volume drops down (not completely gone) and will come back on its own after a while or will come back immediately by switching from 'ON' to 'STANDBY' then back to 'ON'. Where do I look for the problem ... have limited testing equipment. Thanks.

Clean that switch with de-oxit, just a little not a lot of cleaner.

On the R-4A this can be caused by C126, 0.1 ufd 200v cap, becoming intermittent. There are two documented cases of this on the Drake List. The cap is electrically located near the input side of the PBT, physically on the small PCB next to V4 (12BA6).

Sorry I can't be more specific, I'm on vacation and don't have a schematic with me.

Does anyone out there happen to have some cases for the C Line?? I got what was a pristine T4XC and R4C, but the UPS Store that packed it didn't put enough packing to do any good at ALL. I need the top and bottom cases for the R4C and the bottom case for the T4XC. These are NOT slight bends, and all are in the area of the front where the metal is folded over, negating a chance to straighten them. I am just sick!!! Awaiting word from the seller, to see if he insured them well, but will need to know if any cases are available.
Thanks,
Don, WB5HAK

From: Ivan
Topic: 4369 Message: 4369

I have an ICOM 746Pro which I would like to use with my L4B linear. I have read that voltages might damage the IC and others. I have an Ameritron ARB704 which I used with my FT950 to Ameritron.

I would be grateful if someone would point me to safely connecting.
Here are the available "ports"

L4B has XTMG AGC OUTPUT (an RCA female)
AMERITRON ARB704 has the following female RCA ports:

AMP
ALC
RADIO
It has also a 5-pin DIN which will interface with the IC746Pro.

The IC746PRO has SEND CONTROL JACK an RCA female #8: "Goes to ground while transmitting to control external equipment such as linear amp. Max control level: 16VDC/0.5 A.

So should I connect the XTMG AGC to this #8 RCA?

Thanks for advice.

Ivan...

What I did is convert the 2 pin VOX connector to a single RCA jack...You can
get the factory kit from here (on eBay)

http://cgi.ebay.com/Drake-VOX-kit-/390181797533?pt=LH_DefaultDomain_0&hash=item5ad8a5be9d

or..

You can buy an adapter cable from here:

http://cgi.ebay.com/Drake-L4-L4B-cable-Relay-/270641971580?pt=LH_DefaultDomain_0&hash=item
3f0384c17c

or

You can make your own.

I use my L4-B with the Ameritron ARB-704 and a Kenwood TS-2000. Of course,
with the B Line I have, no special relay or cables needed, other than the
VOX cable.

4372. Drake C Line for sale

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-09-29 18:48:06 UTC
From: wr5rr@sbcglobal.net
Topic: 4372 Message: 4372

Drake C Line

I want to sell my C-line because I can't justify the little operating time I use it. It's too nice to set around. Someone who will use it more should have it. I would rather not ship the Drakes for obvious reasons. I am in central Oklahoma and would be willing meet a buyer half way, a reasonable distance of course. If interested please contact me off list and I can send pix and exchange cell phone numbers to further discuss the equipment.

R-4C S/N-16805, this unit was completely gone over by Jeff Covelli WA8SAJ in January of 2007. It is a 9+ condition. I have the paper work and manual for this unit also. Normal band crystals 3.5, 7.0, 14.0, 21.0, 28.5, plus there are 12 extra crystals in the- RX, Xtals: 1.5, 3.0, 9.5, 14.5, 15.0, 27.0, 28.0, 29.0, 29.5, 10.0, 18.0, and 24.0. The receiver has the 2.4, 1.5, and .5 khz filters. $395 OBO for R-4C.

TX-4C S/N-21608, this unit was also completely gone over by Jeff Covelli WA8SAJ in January of 2007 and it also has had only about two or three hours of use since. The condition is 9+ out of 10. Normal band crystals 3.5, 7.0, 14.0, 21.0, 28.5. It is paired with the AC-4 power supply S/N-44734 which was upgraded to solid state (AC-4R) in January 2007 by Jeff, and the the MS-4 cabinet. I will include the MS-4 to the buyer who buys all on a package deal. $395 OBO for R-4C and AC-4R.

All connecting cables included for transceive or separate operation. I have the repair paper work and manuals for the R-4C /TX-4C.
Asking $750 OBO for all including MS-4.

I also have the following items used with the C-Line:
Audio-Technica P-16 microphone with matching transformer for the TX-4C, with a Heil low profile short boom. $40
Drake 7075 microphone. $50
Key-All to allow a solid state keyer to be used with the TX-4C. $25
Drake W-4 watt meter with the K4DPK PEP kit installed. $50

Total for all listed is $875

4373. Drake T-4XB Connections to Heathkit SB-220

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-01 01:32:37 UTC
From: John
Topic: 4373 Message: 4373

Greetings.

It's fascinating that KB1STH asked his question since I just logged in to ask my question about going the other way. I want to be certain about my connections of my beloved Drake T-4XB transmitter to a Heathkit SB-220 linear amplifier (still going strong since I assembled it back in 1976).

Pins 5 and 8 on the T-4XB connect to the SB-220 antenna relay connector. The SB-220 carries 120 VDC on this line. Are the T-4XB relay contacts capable of handling this voltage? (I have not found any ratings for these in the manuals.)

Pins 3 and 7 on the T-4XB connect to the SB-220 ALC connector. The SB-220 carries 60 VDC negative threshold voltage on this line. I know that the T-4XB requires negative going transmit AGC voltage on pin-3 to prevent flat-topping of voice peaks due to over-drive. But again, I have not encountered the voltage rating of the T-4xB.

Does the collective have any insights into this?

Thank you in advance for your help.

John

John -

I don't have any specifications for the relay contacts in the T-4XB. The plug-in relay in the C Line, similar construction, has contacts that are rated at 2A at 28 VDC or 2A at 155 VAC.

Just for reference the L-4B keys with 30 VDC @ about 60 mA. So we can assume that is a 'safe' load for the relays in the T-4X(any) transmitters.

All that aside, especially in the T-4XB, I'm sure you've examined the location and wiring of that relay, and perhaps have even considered what would be involved in replacing it, IF you could find a suitable electrical and mechanical replacement. Drake offered a "repair" kit, consisting of a plug-in relay as used in the T-4XC, along with a small PC board and several pages of instructions on converting the 'B'.

Now. External, 'soft-key' or other interface units are pretty inexpensive, and if THEY fail it's a rather simple repair, with considerably more modern parts. Personally I would MUCH rather 'baby' those relay contacts so they would hopefully outlast ME.

The ALC connection is either a lot simpler, or more difficult, depending upon how you look at it. For one, you really SHOULD have a scope to verify that you're not overdriving your amp into distortion. Actually, it's likely that you wouldn't be able to over drive the SB-220 with a typical T-4X(any). The ALC is negative on the T-4XB, and since it's a 'closed loop' system, e.g., IF the amp is over driven, it puts out a negative voltage that reduces the drive (output) of the T-4XB proportionally.

In the L-4B, the RF input is sampled, rectified and used to offset a positive bias set by the front panel "AGC" control. The SB-220 seems to have a similar setup except the threshold is fixed by a resistive voltage divider. It's reasonable to assume that drive for the tubes would be about the same, although again you need a scope to see if the divider sets the threshold properly. Wouldn't be a big deal to adjust those resistors, but most likely not required.

Thanks for your response, Garey.

I like your idea of an external keying circuit. I think I will head that direction.

Yes - I do have a scope on the output of the linear to spot check modulation - usually after a QSY to a different band.

I subscribe to the theory of not pushing everything to the limit, since a few watts less seldom makes any difference on the other end. I used the linear when I was in Ecuador to help with third-party phone patches, but now-a-days state-side I just rag-chew with other hams. But I would like to have it available in case I want to use it with the Drake twins.

Thanks again for your help.

4376. TR-4C PTO dial adjustments?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-01 21:22:37 UTC
From: w1kilofoxtrot
Topic: 4376 Message: 4376

The previous owner soaked the PTO gearset in oil. I took it apart, and got it pretty well cleaned up. It's very smooth, but I can't get the dials aligned again. The procedure on WB4HFN's web site shows adjustment arms that let the gears unmesh, but I don't have them on my unit. (SN 34674)

Anyone else run into this? Any helpful hints?

Steve -

Interesting, I don't think I've ever seen a PTO in a TR-4C without the levers. But then I haven't seen all that many TR-4Cs!! :-) All the levers do is to apply pressure to the side of one of the idler gear shafts. The shaft 'bearing' in the front plate of the PTO is elongated to allow the shaft to move laterally to disengage the gear. They are the ones with a spring to pull them back into mesh.

Easiest is to set the PTO to a known frequency, either by measuring the PTO frequency itself or by tuning in a known marker, then disengage the dials one at a time. When disengaged they will rotate freely and you can put them where the belong.

Garey,

Lucky me. Without those levers, it's almost impossible to re-set the front dial so the holes line up for the little rivets. I guess I'll have to keep trying...

I've got a frequency counter looking at the PTO output, so it's easy to know where the dials ought to be. It's the mechanics that are messing up my progress...

Steve -

You put the rivets in first! The entire hub rotates once the idler
gears are disengaged... You should be able to disengage them by pushing
the idler gear shafts to the side away from the rest of the gears to
allow the hubs to rotate freely.

From: w1kilofoxtrot
Topic: 4376 Message: 4382

Ahh, Gary, it would be that simple if I had idler gears that would move out of the way. But, I seem to have been blessed with a PTO assembly where the gears were fixed in place, and the only thing I can do is slip the back dial by removing the clip ring and wiggling the whole assembly around. So, I can set the back dial (with some difficulty), but not the front dial.

From: ganders52
Topic: 4277 Message: 4383

I have two filters for the TR4/TR4C. If you are interested send me an email at my home account (kg6yv@...). These came from a working TR4 that had an upgrade to the INDRAD filters.

--- In DrakeRadio@yahoogroups.com, "w1kilofoxtrot" <w1kf@...> wrote:
>
> Finally got back to this. Decided to short out the filters, and things are working much better. There was very little coupling in the 'X' filter, so could not get any output from the rig until I shorted it out. Dummy load is nice and warm, now! Receive is not bad either, but of course I need the filter to knock out the opposite sideband, so this is a test-only proposition.
>
> It does mean I need a new filter, though. Anyone parting out a TR-4 rig? Or, should I simply use some KVG filters, available from a vendor in Israel? I think the KVG are 8 pole, high quality units, but I'd have to fabricate a new bracket for them. I'd rather keep it original, if I can.

A follow up. Seems my vision is not all that it should be. My PTO does, in fact, have a slotted hole for the idler gears. That means I -can- finagle the gear set in order to line up the two dials.

My PTO does not have the fancy levers shown in some pictures, but I've gotten it done just the same.

Yet another step complete!

Now, I've got to get the carrier oscillator on frequency. It's about 800 Hz too low, so I can't get it centered between the two filters. It would have to be too low, right? I can't just pad it up with some paralleled caps...

Vic -

That sounds about right. It's correct electrically, and 9mm is about
right for the base diameter.

If you end up having to order them, order #755 as they will last
'forever' and are completely interchangeable with the #47. 20,000 hour
life for the #755 vs 3,000 hours for the #47.

Steve -

You just need three pairs of 'reading' glasses, an Opti-Visor, and several magnifying glasses like I do!! :-)

As for your CO problem, clean the contacts of relay K2, (in the CO compartment, on the back wall of the chassis.) Also make sure it operates when you switch modes. Crystals almost always drift HIGH with age, so likely something else.

Garey,

The good news is that the relay is working as intended; it switches when in CW-X mode, as it should, and shifts the frequency up around 800 Hz or so. It's on receive that it's low.

I think I really can't get much further until I resolve this, since I don't want to peak everything up, and then find I've shifted the center frequency.

I wonder if one of the ceramic capacitors in the area has drifted. I cleaned the chassis mount variable capacitor for the crystal calibrator, but the one for the CO is tougher to get at. Guess I'll just have to give it a whirl!

I am learning this rig in much more detail than the old TR-3s that I had!!

Vic -

Looks right. According to Maplin, the 6.3V at 150 mA (BT81C) is also
rated at 20,000 hours, comparable to the #755. The physical dimensions
are also correct.

I am Ron, K0IC, in Essex, Iowa. I used to own a Drake TR-3 and a Drake SPR-4. I still own a Drake C-line which I plan to keep as long as I live. I am in the process of recapping the R-4C and I plan to upgrade the AC-4 power supply. I try to keep updated on what is going with the Drake lines. If I can afford it might like to have the Drake B-line but that is not affordable as I have health problems and I am on SSI. Other than that I am satisfied with what I have. I worked in broadcasting for twelve years before insurance and other problems got me in going another direction.

To Garey,

The other thing I have found is that modern #47 bulbs don't seem to be as durable as the old ones. When I sent my TR-4 to Jeff Covelli, he replaced the original bulbs with new ones. They promptly burned out after less than 2-hours run time (Both burned open). Jeff included the old ones. I put those in, and the light has returned permanently <grin>.

Have fun and good luck!

My SP-600-JX;s wrere lamp burners. I suspect it may be
due to the increase in line voltage in many areas. All these
receivers were designed at a time when the "nominal" 117
volts really was 117, now its closer to 122 in many areas.
One can drop the voltage to the receiver using a tansformer
but its easier to use overvoltage lamps like the one Garey
recommends (actually about an 8Volt lamp) or put a dropping
resistor in the lamp line. The latter was specified in the
military modification work orders for the SP-600-JX so its a
legitimate change. One of my receivers came with it
installed and I installed it in the other. In both cases the
lamp life went from a couple of months to practically
permanent. In general, lowering the voltage to an
incandescent lamp or tube by 5% doubles the life without
reducing brightness much or, in the case of tubes, emission
much.
Now, having said all that your lamps burned out much
too quickly. I would check your line voltage. Do it at
several times during the day because line voltage typically
varies a _lot_.
I have no idea where lamps are made now but I've found
that much stuff now comes from China where its made to very

low standards with low cost being the _only_ objective.

Welcome, Mac,

I'm Grant, KT6L, in San Diego, CA, retired for 5 years; 1st real receiver I had was a 2B and still have one; have the "B" line, SPR-4, FS-4, and TR-7. These Drake radios are gold.

Also have a Yaesu FT-857D and about half-dozen QRP rigs, also a couple of VHF/UHF HTs.

Was a radio operator in the Army (82nd Airborne and 8th Infantry in Europe).

This list has tremendous knowledge and expertise which I've found helpful more than a couple of times.

From: Dick KF4NS
Topic: 4407 Message: 4407

Where is the best place to measure the 9mhz osc. freq? The method I used before to set it was to inject a sig gen at T-11 and zerobeat. I have a pretty accurate freq counter and would rather do it that way.

I guess I could just test it at pin 1 of V16 but I don't trust my 8db wideband buffer/amp to much.

Dick -

I pick it up at the arm of the Carrier Balance pot. Any kind of probe
on Pin 1 of V16 will shift the frequency.

Keep in mind that the 'final' setting is made to center it between the
two filters, which may not be exactly 9 MHz. You just have to get it
close enough to be sure it's not set outside of either filter! :-)

I'm faced with a similar problem at the moment. I just ran the Drake filters on my VNA, and find that the 'center' frequency really wants to be 9.001218 MHz. But, I can't make my carrier oscillator go much above 8.998 MHz. Kind of ruins the frequency response of the USB filter. Of course, my USB filter is trashed anyway, with a deep null right in the middle of the response curve.

I've installed a set of KVG filters for the time being, but they still want a carrier closer to 9 MHz than I can get. The offset also means I can't get enough through the filter to give me any power output on transmit.

I've been using the center of the carrier balance pot for measurements. Make a great test point!

4410. TR4C weird xmit trouble

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-04 22:09:26 UTC
From: Dick KF4NS
Topic: 4410 Message: 4410

Ok guys, I have this black cloud over me right now. The radio is receiving fine (other than the filter defect) and I decided to get the xmit completely checked out before I wrap it up.

All of a sudden while on 20M band position and checking the PS bias, it jumps intermittently to 400-600ma with no drive, sideband switch in ccw position (actually makes no difference), dummy load connected and no mic or key connected.

After quite a few hours pulling out my hair (just the gray ones) I tweaked the TUNE control and the trouble went away. I tried full ccw and cw and everything in-between on all the other bands and no effect, only affects 20M and only when the TUNE control is between 1 and 6. I checked and rechecked the band switch contacts over and over. What the heck, I even tapped all the tubes and every other silly thing. Given time and a few cups of coffee I can usually make sense of these kind of things but not this time. HELLLLLP!!

Garey,

In the 'you learn something new each day' department, I offer up the following: in my case, the CO crystal drifted lower with age. By rather a lot, actually. I replaced it today with a crystal Fox was kind enough to send me when I was running down a problem with my old TR-3. It's spot on at 9.000000 MHz, and that is exactly the center of the KVG filters I've temporarily installed in the TR-4C. I'm getting 150W indicated on 80-15 meters, around 100W on 10M, where I was getting 5-10W before, because I was on the slope of the filters. And the sound is lovely. Why not leave them as is? Well, I had plans for the KVGs in a little project I'm building. I think I've found a source for a pair of Drake original filters, so I'll put it back as it was.

But, lest I get too cocky with all this, I also found out that I reversed the filters. That is, the USB filter is where the LSB ought to be, and vice-versa. Works a real treat, but it's all upside down!

Where's that soldering iron got to?

4415. PU1WJH - Drake TR4 problem - Plate current..,. bottom of scale

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-06 21:06:53 UTC
From: caviloso
Topic: 4415 Message: 4415

HI!

My TR4 has a problem. The plate meter board ever hit the bottom of the scale. I believe the shunt resistor in parallel with the meter must be opened or changed the value. I need to know if the shunt may be the R13* or R452 or another, but I can not find them physically under the chassis. Would like someone can help? Thanks from Rio de Janeiro!

Topic: 4415 Message: 4416

Ricardo -

Actually the shunt is BOTH R45 and R13*. R45 is 2 ohms, and R13* is typically 15 ohms. R45 is the shunt, and R13* is selected to 'calibrate' the meter to read accurately at 100 mA. The two resistors are connected in parallel and both are located on the small board just opposite the feedthrough terminals on the PA shield. It is the board with the large film type capacitor with the white, epoxy end. R45 is just to the right of this cap, and R13* is on the other side of the board.

The usual failure is that these resistors go UP in value, causing the meter to read UP scale.

Subject: [DrakeRadio] PS7 Filter caps Source

Looking for a source for the Mallory CGR 15000MFD 30V filter caps in my PS7. Non stock at all the regular sources and minimum orders are from 25-80pcs.

Thanks

Curt

4418. TR4C neutralization

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-06 22:34:52 UTC
From: Dick KF4NS
Topic: 4418 Message: 4418

Please refresh my memory. I prefer to do it with the plate/screen V removal procedure, not the complicated step in the manual, but I forget, do you tune a 10M freq for max output or min plate current in the first step? I already tuned using the max output method and removed power and bled the supply lines but before I remove the voltages I want to be sure I chose the right method.

I believe that the voltages are removed at C75 for screen and the insulated feedthru for HV. Correct me if I am wrong.

thanks and 73, Dick KF4NS

4419. bad 10M TR4C crystal

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-06 22:51:40 UTC
From: Dick KF4NS
Topic: 4419 Message: 4419

While trying to set up for the neutralization, I tried to tune up on 29.1mhz and found out that although the 43.6mhz crystal is the newest one in there, receive is dead and of course xmit is the same. All crystal contacts were cleaned and Deoxit applied some time ago. All the other crystals work ok.

Is there a way to test the crystal (and any other crystal) without building an oscillator?

bottom of scale

Ricardo -

Actually the shunt is BOTH R45 and R13*. R45 is 2 ohms, and R13* is
typically 15 ohms. R45 is the shunt, and R13* is selected to
'calibrate' the meter to read accurately at 100 mA. The two resistors
are connected in parallel and both are located on the small board just
opposite the feedthrough terminals on the PA shield. It is the board
with the large film type capacitor with the white, epoxy end. R45 is
just to the right of this cap, and R13* is on the other side of the board.

The usual failure is that these resistors go UP in value, causing the
meter to read UP scale.

From: captcurt2000
Topic: 4413 Message: 4422

Hi Dennis:

I'm pretty sure those would work...there are many like that to choose from...but the spec on those caps isn't even close to the CGR except in capacity and WV. The CGR's have very low ESR and very high ripple current rating. at least a factor of 3x better than the snap ins.

Of course they are less than 4 buscks also :) and the CGR's are gonna be 30 something IF I can find them somewhere.

I might be forced to make up a mounting board and connection terminal for a set of snap ins in order to get the rig on the air.

Kind of doubt I could find a dozen other guys to order a minimum quantity of fresh OEM exact CGR's for the PS-7s..maybe tho.

Thanks for the suggestion, I might have to go that way in the end.

Curt

4423. Bad crystals in TR-4C

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-08 13:58:52 UTC
From: w1kilofoxtrot
Topic: 4423 Message: 4423

Well, the adventure continues. Turns out not all bargains are a good deal...

I wondered where the calibrator signal went on 40M, and I found it, around 10 KHz off. Checked the ultra stable and accurate 21.5 MHz crystal, and found it at 21.488 MHz. That's the second crystal to go low with age. (The 9 MHz carrier oscillator was off too.) The 15M crystal is right on at 35.5 MHz, and the one 10M crystal, which should be at 43, is at 27. Oh, joy...

It looks like I'm in the market for a bunch of TR-4C crystals. I could buy brand new ones, but it would be cheaper to get a new rig :-)

So, if anyone has a TR-4C 'project' that they are ready to give up on, please let me know, on or off list...

I'll be on 80M and 20M with this rig as soon as I re-wire the plug on my good old Turner 454C. As for the rest, well... it's in your hands at the moment!

Dave -

There are ten to start! :-)

They are standard 0.125" (1/8") dia steel ball bearings.

Your local ACE or True Value store should have them in their specialty hardware drawers.

Yes, back off the screw just enough to get them in. Some Lubriplate or White Lithium grease should hold them in place. Tighten the screw only enough to take out the lateral play, don't over-tighten.

4428. T4XB Bandswitch

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-08 17:13:30 UTC
From: ALAN PHILLIPS
Topic: 4428 Message: 4428

The bandswitch has always been difficult to move. You can hear the phenolic scraping. It has not been cleaned with anything. I installed a new bandshaft last week and lubed the ball bearing with lithium. I noticed that the first wafer metal spacer was bent so I made it parallel to the others. I just about lost it when aligning the crystal switch. So, I gained nothing. I visually tryed to see if the round portion of the phenolic rotates freely,

Can the switch wafers be swollen with age? Has this happened to anyone else besides me? Is there a cure? These wafers are delicate and repositioning them to center the shaft may make things worse. I recentered the first group of bandswitch wafers closest to the panel and re-tighted down the top holding nut and things got worse.

Thanks for your help.

From: Garey Barrell
Topic: 4428 Message: 4429

Hi Al -

The T-4XB BAND switch is always a little hard to move because of the right angle drive.

Some spray 'cleaners' will cause the phenolic wafers to swell, but I'm not aware of any age related swelling.

They will sometimes rub due to the fixed wafer hardware loosening over time. Best way to work on this is to loosen ALL wafers at once, just enough to allow you to move them with a little pressure, and then go through multiple iterations until they all line up at once. It's best to firmly shim the front end of the shaft in the chassis hole to keep it in the same orientation. Usually it's 'natural' position in the hole is the right one, but messing with the various fixed wafers can put slight pressure on the shaft, moving it just enough to screw up the NEXT wafer's position. One thing to check first, are you SURE your new shaft is straight??

I've only seen one unit with this problem that had NOT been 'sprayed', and was able to recover it by going through the above for an hour or so!

Perhaps others have ideas?

Al -

Sorry, I was thinking of the wrong detent arrangement. The detent is of course at the front. Try to center up the rear-most wafer, it's usually pretty solid from the capacitors, then loosen the rest and align to that.

Most likely the rear wafer is OK. Even if the hardware loosens, the cap
leads are stiff enough to hold it in the right place unless someone has
been leaning on it.

The basic idea is you have to get the two ends aligned with each other
and then shift the rest, including the R/A drive, on that line.

Most GDP's will oscillate if you plug the crystal into the coil
terminals. Obviously it only works with two pin coil versions, but
that's most of them. Some GDOs have three pin coils for extended range,
and some of those will work also if you get the right two pins!

I will try this on my Millen GDO. It does have three
pins but only two appear to be used. Actually I have no
idea of what the third pin is for.
```

BTW, I received it without the highest frequency coil, a hairpin type. If anyone on this list has a spare please contact me off list. I can make one but would prefer to have an original if possible.

BANDSWITCH REPAIRS SOLVED:

Well, Garey, you will never believe this. I took some 5% deoxit and sprayed some in a container and used a chemtronics foam tip to lightly dab part of the available surface of the contact ring on each wafer. I was only able to clean part of that circle. the amount of liquid on the foam tip was almost nothing when I put some on my hand to check the amount.

Yet, the bandswitch noise is gone and it operates perfectly.

No friction or noise between the detent.

Also, it was good to talk to you on the TX.

Speaking of the TR4. If I adjust the cap for equal pitch of the "hiss" between both sidebands and its close but not the same, doI have a drifted 9mhg crystal? Is it possible to get it right on?
thanks. kc9ys, al.

Subject: [DrakeRadio] Bad crystals in TR-4C

Well, the adventure continues. Turns out not all bargains are a good deal...

I wondered where the calibrator signal went on 40M, and I found it, around 10 KHz off. Checked the ultra stable and accurate 21.5 MHz crystal, and found it at 21.488 MHz. That's the second crystal to go low with age. (The 9 MHz carrier oscillator was off too.) The 15M crystal is right on at 35.5 MHz, and the one 10M crystal, which should be at 43, is at 27. Oh, joy...

It looks like I'm in the market for a bunch of TR-4C crystals. I could buy brand new ones, but it would be cheaper to get a new rig :-)

So, if anyone has a TR-4C 'project' that they are ready to give up on, please let me know, on or off list...

I'll be on 80M and 20M with this rig as soon as I re-wire the plug on my good old Turner 454C. As for the rest, well... it's in your hands at the moment!

73,
Steve

OK. Must have been a much 'softer' scrape than I understood. Again,
some spray cleaners, when they're used like a pressure washer (!) will
take off the natural lubrication of the phenolic switch wafer.

Glad it was (eventually) an easy fix!

Close is about as good as it gets. The filter passbands are always a
little different, giving a different 'pink' to the noise.

If you want to play, use a noise generator with one of the PC audio
analyzers such as Spectrogram and then you'll be able to see the passbands.

Of course you can always just plot the filter response by tuning across
the calibrator signal and using a counter to plot the points.

Thanks Garey:

Well this morning, my bandswitch turns easyier but not as easy as last nite. the light coating may have dissapated, but the switch is much better. Would you recommend a second light swab of dioxit or let sleeping drakes, (dogs), lie?

You might try a little GC Tunerlub. Also, many years ago Boonton Radio, makers of the famous Q-Meters and also signal generators, experimented to find the best material to coat switch contacts with, the winner was Lubriplate. It had the lowest contact resistance and longest life. Currently Lubriplate is made in several types, I am not sure what it was when the Boonton research was done. Tunerlub is a clear grease, non-conductive. Its used after cleaning with something like Deoxit. I've used it on worn rotary switches which did not stay quiet more than a couple of days after using contact cleaner. After treating with Tunerlub they have stayed quiet for years.
Also, check for binding in the gear coupling of the switches and lubricate the detent mechanism, which on the Drake is, I think, on the back. Light grease is right for this. Shaft bearings should be lubricated with oil since grease will not penetrate into them. Also, use oil on surfaces which do not rub enough to keep grease distributed.

Alan, I am not near Garey's level of expertise on much of anything, but DeOxit is NOT a lubricant, it is a contact improver. I wouldn't put any more of it on the wafer itself, but maybe some light lubricant of whatever type Garey recommends. He said as much in his post if you read between the lines, saying something like "blasting the contacts with cleaner takes away lubricant". I'm not sure what is made in current production, but there used to be many light lubricants used in TV tuners that might have been appropriate. The key word though is "light application" like you did before.

thanks Richard.
Does the tunerlube get placed on the rotary silver contact of the wafer switches?

I'm not real fond of DeoxiT on phenolic wafers. It's probably ok, but
it's not going to hold up long.

I think I would try a little candle wax (birthday candle) lightly rubbed
on the edges. You could try a little silicone, which might work fine,
but still a little leery of putting any kind of oil on the wafers. I
don't know if they are lubricated in any way when new, but I would guess
a wax if anything.

Have you put a drop of light oil on the bearing through the panel?

Looks like I'm a little late to the party! :-)

Richard has some good suggestions. I hadn't thought of Tunerlub, but it's probably ok, applied
SPARINGLY!

I wonder if FaderLube would work? It's designed for pots, rotary and slide, which have phenolic
bases. It cleans and leaves a nice 'lubed' feeling to pots. I may have to try some of that.

Whatever you use, use the absolute minimum. Nothing makes a parts rig like a blown bandswitch!! :-)

Hi Gary and Hi to all that replyed with good suggestions.
I need to clarify a few things because I may be on the wrong page!

I did not lube or clean any phenolic parts on the bandswitch at all. I used a slightly damp foam tip on the silver round or semi-round rotary contact that is on the phenolic switch, being carful not to get any deoxit on the wafer parts, at all.

So please help me understand, the use of the candle wax or as suggested, the tuner lube, it it to lube the actual silver contacts or is it for the round phenolic part of the switch that rotates with some friction as it turns.
thanks for your help.

Ok, two different things!

The candle wax and silicone that I was referring to was for the phenolic wafer rubbing.

For the contacts themselves, DeoxiT works good, but you need a little more of it. A small drop on each fixed contact is best, but of course it's difficult to get to all of them. So a good drop on the ones you can get to, and then exercise the switch to spread it around. I use DeoxiT D100L, which leaves a nice lubrication after cleaning. I think the D5 spray also has lubrication, but with the spray it's hard to get 'just a little'. I used to use the 'spray some in the cap' technique, but the needle applicator is a lot easier. It's possible that the lube is not deposited from the D5, but I think mainly you just need a little MORE... Never thought I'd say that, did ya!?!? If you can get your hands on a syringe, that makes it a lot simpler.

I don't think you can get too much _on the contacts_ , just minimize how much gets onto the phenolic.

4448. FS: Unique Drake Service Supplement CDs

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-09 21:07:32 UTC
From: Garey Barrell
Topic: 993 Message: 4448

Here is the information that Drake left out of their manuals!

Unique supplemental service information CDs available for the Drake TR-4, TR-4C/Cw/CwRIT, B and C
Lines, 2-C / 2-NT and the 2-B receiver.

High resolution color photos of the under chassis and individual PC boards of each unit, with all
parts identified and keyed to a parts list make it easy to locate any component. No more trying to
trace wires through bundles, etc. This information is not available elsewhere and really makes a
difference in servicing these units.

These CDs are NOT just scans of the original manuals that were included with the equipment when new.
High resolution scans of the original manuals ARE on the CDs, along with scans of manuals for
associated equipment such as the C-4, FS-4, MN2000, L-4B, W-4, etc.

Samples of these pages (at reduced resolution) and purchase information are at <www.k4oah.com>.

Garey:
Thanks for all the help. I just found a mini-tube of G100L in my toolbox!
I presume that I could put a drop with a small screwdriver on the silver round rotary contact?

73's al kc9ys.

Al -

Ok, two different things!

The candle wax and silicone that I was referring to was for the phenolic wafer rubbing.

For the contacts themselves, DeoxiT works good, but you need a little more of it. A small drop on each fixed contact is best, but of course it's difficult to get to all of them. So a good drop on the ones you can get to, and then exercise the switch to spread it around. I use DeoxiT D100L, which leaves a nice lubrication after cleaning. I think the D5 spray also has lubrication, but with the spray it's hard to get 'just a little'. I used to use the 'spray some in the cap' technique, but the needle applicator is a lot easier. It's possible that the lube is not deposited from the D5, but I think mainly you just need a little MORE... Never thought I'd say that, did ya!?!? If you can get your hands on a syringe, that makes it a lot simpler.

I don't think you can get too much _on the contacts_ , just minimize how much gets onto the phenolic.

From: mydogchillroy
Topic: 4450 Message: 4450

Hello Everyone,

My name is James (AJ4VP)from Falls Church, VA. I recently took delivery of a R-4B, T-4XB, MS-4 and W-4. I look forward to learning more about Drake radios from my use of the radio and from correspondence with you all. I am in the process of taking stock of what I have, cleaning the equipment and getting it ready for use.

73
James

Welcome to the group, James. You will find a wealth of information on this group about your Drakes and tube gear in general. If you are new to tube gear, please be careful with the high voltages you will encounter in the service/alignment of it. I too have a "new to me" T4XB/R4B/AC4/MS4 in UPS right now heading to me. One tip I would give is that if the AC4 is original, I would go to the Heathkit Shop (www.heathkitshop.com) and look at their AC4R upgrade kit. The capacitors in the old AC4's are getting old enough that they fail regularly with disastrous results. There are other things to check, but those are CRITICAL.
Again, welcome!!
73,
Don, WB5HAK

That'll help. Be sure and let it 'dry' before applying power. It's a
'little' flammable!

4453. Nearly Free Ham Band Crystals II

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-11 12:48:51 UTC
From: Bry Carling
Topic: 4453 Message: 4453

Thank you to everyone who responded about the groups of crystals.
They were all sold. I have a few more if anyone is interested, great
for homebrewing and experimenting "AM CW delight" - as follows:

(these will only be sold as groups)

GROUP 1 - hc16 crystals on: 7174, 7185, 7200, 7212, 7244 kHz
Available for $5.00 plus shipping

GROUP 2 - hc16 crystals on: 28444, 28444, 28555, 28735, 28785, 28866,
29011, 29444 kHz
Available for $8.00 plus shipping

GROUP 3 - FT243 crystals on 7073, 7100, 7125, 7140, 7175, 7200, 225,
7244, 7275, 7286 kHz
Available for $12.00 plus shipping

GROUP 4 - FT243 Crystals on 7075, 7100, 7106.7, 7125, 7140, 7173,
7175, 7224, 7275 kHz
Available for $12.00 plus shipping

GROUP 5 - FT243 Crystals on 7073, 7125, 7125, 7140, 7151, 7174, 7175,
7200, 7225, 7300 kHz
Available for $12.00 plus shipping

Contact me off the list via e-mail please...

73 - Brian, AF4K

Yes, I am not sure if its conductive but it seems to protect the surfaces from corrosion once they have been cleaned with something like Deoxit. The bearing shafts of pots and switches should be lubricated with some sort of light oil beause grease will not penetrate. I am not sure what is in Deoxit but it seems to have a degreaser and a reducing agent. The degreaser will remove lubricant. Most multiple switches have three parts, a shaft and bearing, a detent, the switch contacts or wipers. The shaft bearing needs oil, the detent probably can be lubed with light grease, the switch contacts may need a light grease or no lubricant. They are intended to be self-wiping.
Tuner-Lub was originally intended to be used in the very common Sarkes-Tarzian turret tuners which were almost universally used in TV sets for decades. I've found it keeps switches quiet for much longer than just Deoxit does. It does not seem to damage Bakelite.
I would use caution in putting anything on ceramic insulated switches. Usually they are used in RF circuits where losses must be very low and insulation strength very high. The ceramic at least should probably be clean and dry.

Welcome aboard, I have the same rig except for the
speaker. I _very strongly_ advise you to get Garrey Barrel's
CD. It has info you will NOT find anywhere else because
Drake _never supplied it_. Also clean, hi-res, PDF's of the
manuals and schematics.
Check out the AC-4 very carefully, many of them have
tired filter caps. They can cause low voltage and high
ripple. The bias supply can cook the tubes if it fails. If
the caps are tired its best to replace the entire inside
with the kit available from the Heathkit Shop. I did this to
mine. However, despite the warnings about the bias supply
the circuit in the modified version is identical to the old
one.
The rigs will meet specs and perform very well.
I would add to your set-up a good antenna tuner and a
good dummy load and power meter. Also, if you can afford
forty or fifty acres in the country for an antenna farm it
will help.

4456. Re: TR4C weird xmit trouble

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-12 17:29:29 UTC
From: Dick KF4NS
Topic: 4410 Message: 4456

I sure hope I am not making a nuisance of myself but I am out of ideas and have tried everything that was suggested, including neutralization (which was ok) and have read the manuals for service and owners over and over for hours, and have studied the schematic for hours and hours.

The original message was for a trouble just trying to set the bias which was fine on all bands but 20M. Since then, I have tried to tune up in the X-CW position and all bands tuned fine except for 20M. On 20M I can get a power out of 150W but the plate current is 600ma, the xmit gain dips the plate current (yes, the xmit gain!), the plate tune cap also dips the current but output drops to nothing, the RF tune acts like the xmit gain should.

The only real defect I did find was R53 1.5K in the plate circuit of V11 was cooked. I replaced it.

This rig has been gone completely refurbished recently with bad tubes replaced, all contacts cleaned and contact enhancer applied, 9mhz osc. set right on, 100khz osc set right on. neutralization set on 10M, resoldered the contacts on the rear wafer of bandswitch, C145 replaced, P.S. upgraded to AC4R.

Keep in mind, ALL BANDS RECEIVE FINE AND TRANSMIT FINE except 20M.

Please help, Thanks and 73, Dick KF4NS

From: Garey Barrell
Topic: 4410 Message: 4457

Dick -

Is this a 'new' transceiver to you? Has it ever worked on 20M to your knowledge? 20M is one of the 'simple' bands, (the other one is 80M,) where Q1, Q2, V1 and V3a are not used at all.

What brand are the final tubes? Are they the same brand?

It sounds like the PA is oscillating. The most common cause is off-brand or mis-matched final tubes. Next is improper neutralization. Next would be a bad bypass cap. There is also a possibility with the TR-4 series of mistuned bandpass transformers. You could remove the PA tubes, or just remove the screen voltage at the third feedthrough from the back on the PA shield under the chassis (C75). Careful, the second one from the back is the HV! Once the PA is disabled, see if you have a correct 20M signal out of the Driver stage (V6).

I suspect if you checked your '20M output', you'd find that it's NOT where you think it is. Does the output peak with the RF TUNE control in approximately the correct place? IF you listen on a separate receiver, is there a signal where the transceiver dial says it is?

Listen on a nearby receiver (a spectrum analyzer would be icing on the
cake; I don't have one either). I'll bet that the PA is oscillating to
beat the band.

Is this into a dummy load? I dunno why the instability on 20 if elsewhere
is OK.

This may be inconsequential to your 20m issue, but on my Collins gear (which is circuit similar), there is more than 1 place to set the load and plate controls to get output and dip but, they are not set at the optimal position which causes plate current jumps and it only happens on 20m. The description and symptons of your problem very closely matches what happens to my Collins rig.

In other words, you are getting output but your tuning controls are in the wrong position.

4460. TR7 1-kHz tone won't stop

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-13 00:02:09 UTC
From: stanleyjungleib@rocketmail.com
Topic: 4460 Message: 4460

Just fired up an estate item and it has a low-level 1-kHz in the audio even when idling that is unbearable. Seems to warble with the digital display. Anyone see this? operator error (even with the volume all the way down?), or a normal digital bleed for this machine? If so, gimme back my R-4C!

Certainly NOT normal; probably some of the experts here will have an idea.

The first thing to do with any "new" TR-7 that is acting strange is to re-seat all the plug-in boards.

Found it! Large blue 1000 uF cap at front right of digital readout has a bad joint. Hard for it not to; it obviously hits the inside cover, and got broken down by shipment! Looks like I'll be settling into this one for awhile.

RESENDING THIS DUE TO WRONG ORIGINATOR ADDRESS (STUPID ME!)

Garey,
This is not new to me. I acquired it in 1995 after it had been stored in a garage for 10 years. No need to tell the tale, you can just imagine. After a physical cleaning I fired it up and it worked fine. Then this year I decided after getting your CD that it was time to do a real restore which I did. I will never say that was a bad idea since it was not even close to good performance.

20 meters had been working at par for the rest of the bands. The finals are what was in there, Sylvania 6JB6 da ALM marked on them. As tested on my B&K 707, the gm was for V8=9000 V9=9500 V10=10500, for what it is worth.
Neutralization went well using my scope with voltages removed from finals. Will do it over but tune up on 28.0 instead of 29.1 just for a do-over again.

By the way, the schematic you recommended was series 35161 but I discovered yesterday that mine is a match for series 42500 even though mine was built in '74 with serial #38145, go figure. It has those goofy brn/blk/wht/silver bypass caps across IF xfmrs T11/T12. Took quite a while to figure out they were caps and not resistors. Never ever saw those things before.

4465. R4B Help

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-14 16:37:08 UTC
From: Don Cunningham
Topic: 4465 Message: 4465

Garey, and all,
Just got delivery of my "dream" R4B/T4XB station over the past two days. T4XB fired right up and works just fine. R4B has something amiss, and I can't quite put my fingers on it (not literally, hi). Symptoms, while trying 40m, preselector will peak WELL on 80/160 area with just noise, no signals. Where it should "peak" on the 40m segment, you can sort of peak signals if they are there, but it is VERY difficult to peak on background noise there like a "normal" R4B. Strong sounding signals are only S 3 to 5, and from the sound they should be S9+. No cold tubes, have "wiggled" all of them in their bases (pencil and eraser, like the old days, hi) and only the 12BE6, 2nd mixer makes any noise in the receiver. I have taken no voltage measurements as yet. Really need to be outside working on the quad, but you know how it is with a "new toy", hi. Any thoughts appreciated. I probably have enough good tubes to swap one at a time, as I suspect this is a transportation failure. I bought it from a reputable ham that used it often.
73,
Don, WB5HAK

I had similar problems with my R4A that were cured by cleaning the bandswitch.

Does it peak OK on other bands?
Some possibilities, not in order of probability:
Pointer on tuner is in the wrong place
Bad crystal
Tuner out of alignment.
Clean the bandswitch contacts

Work all the screws that make ground contact
If it works on one band its not tubes.

Also, use the calibrator for checking. It feeds directly
into the antenna input and gives you a signal source
independant of the antenna. Its weaker at high frequencies
but is still quite strong even at 10 meters. There must be a
shorting plug in the mute jack if its not connected to the
TX for the calibrator to work.

Update, switched to the transmitter VFO and all is well. Signals peak well, transmitter tunes (wouldn't using receive VFO), so I'm on the right track now. Thanks for the ideas. I didn't tell all, I have the transmitter hooked already to the R4B and got the transmitter going with the "spare" R4B last night, so have checked cables, etc. I've been playing with these since about 1975 or so, but just wish the memory was as good as the gear. It lasts, but the memory doesn't, hi.
73 all,

Don -

Either the BAND oscillator or the PTO are not running. When the
Preselector peaks, you're peaking on the 5.645 MHz IF. Tuning the PTO
doesn't change the frequency...

Probably the BAND oscillator. See if you can hear it (18.1 MHz for 40M)
on another receiver. If not, find out why not! Most likely BAND switch
wafer that switches the crystals.

If the BAND oscillator IS working, then the PTO isn't. PTO 5.455 MHZ at
000, 4.955 MHz at 500. Scope or other receiver.

BAND osc at 18.1 MHz, -5.455 (PTO at 000) = 12.645 MHz out of Premixer.
Injected into 2nd Mixer, 7.000 MHz signal from Calibrator = 5.645 MHz IF.

Transmit control in TRANSCEIVE injects Premixer signal at 12.645 MHz
directly into the 2nd Mixer. BAND and PTO not used!

Well, Garey, you are right on as always. I replaced V8 with a NOS 6HS6, same problem. Wiggled the xtal/vfo switch on the side and that was it!!! Dirty switch contacts, so all is well. Lesson re-learned. Isolate the problem and KISS (keep it simple stupid, for the new guys, hi). By the transmitter VFO working, I had it isolated, so it was a matter of checking from there. Thanks to all for jogging the old memory. AND, the good ham that sold this to me made a call to let me know he thought it might be the xtal/vfo switch, hi. Still some good ones out there.

I DID IT ! I DID IT ! I DID IT! HAPPY DAYS ARE HERE AGAIN! Please excuse my slurred speech but I just finished a bottle of champagne.
hi,hi

I cannot thank all you guys enough for all the great advice. I learned so much about the operation of the Drake TR4C. You can never know too much. Maybe I will be as good with Drake as with Heathkit. One can only hope.

I rechecked everything again, the switch wafer contacts one by one, the vari caps in the finals, all the pots, flushed the neutralization pot with alcohol and spun it around, etc. etc. The 20M output during the trouble was on the exact frequency of the VFO dial.

Then while checking for a firm seating of all tubes in their sockets, I touched V3 6EA8 MIXER/CATHODE FOLLOWER and heard awful static in the speaker. I wiggled the coil under the socket and the same result. Then I inserted my 9-pin socket test adapter and put the tube in that. HOOOOOORAY! All is quiet. I tuned up on all bands and had good output on all bands except 10M using the X-CW position.

I know I read somewhere but cannot locate it now, explaining the xmit output difference in X-CW as opposed to SSB. Can someone explain?

I will now go back and check the CO, carrier balance, neutralization and tweak the V3 pin sockets with my handy dandy stainless steel fine point dental pick and make sure all pin connections are soldered good and maybe for good measure, just resolder them all to make sure.

thanks so much and 73, Dick KF4NS

The crystal switch is so obscure that unless you
actually use it it tends to get overlooked. Since it has a
lock tab on it so I suspect most never get excercized.

You are absolutely right, Richard. Those contacts get corroded over the years, and cause trouble. On the TR4 series, there is a similar switch on the side to hook up an external receiver. Causes the same troubles. I have had the rig on 40m most of the afternoon/evening and enjoying that great Drake sound!!! Now trying to find a microphone all like with it. Two have flunked, several to go, hi.

Well, what kind of sound do you want? The filters in the
transmitter are pretty narrow. I tried a number of mics on
my T4BX and find the plain old D-104 works about as well as
any other. I mean the plain-vanilla one without the
amplifier in the base.

From: Don Cunningham
Topic: 4478 Message: 4478

Dick,
Remember ALLLLL the stuff you had to do to make it work. I dug my TR4C out of retirement the other day and couldn't get it to transmit :>(, so I may be needing some "expert", recent "been there, done that" opinions!!!! I do run the RV4C with it, and didn't have it plugged in at the time, hummmmmm maybe that was it???? Another day.
73, and congratulations!!!

Dick -

Congratulations! Always nice when one 'behaves' again.... :-)

The TR-4C works a little differently in CW/TUNE than the T-4X(any).

Essentially the Carrier Oscillator is shifted by about 800-900 kHz to put it within the passband of the LSB filter. A 750 ohm resistor (R72) is inserted in series with the Screen supply for the PA, limiting the Final plate current. The Balanced Modulator is unbalanced by a DC voltage derived from the XMTR GAIN control and the audio oscillator (V2) is fed to the SIDETONE & VOX functions.

The biggest difference is that the audio oscillator is NOT applied to the Balanced Modulator to generate the TUNE signal as in the T-4X(any). The Screen voltage to the PA is also reduced in the TUNE mode, but NOT in the CW mode.

4480. Re: testing your crystals

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-15 19:57:12 UTC
From: Dick KF4NS
Topic: 4480 Message: 4480

This may not be the answer for everybody but it worked great for me.

If you have an MFJ antenna analyzer (or other brand) at your beckon call, attach a 50ohm resistor to the center pin of the analyzer and the other end to one side of the crystal and the other side of the crystal to ground on the analyzer.

Tune around the marked frequency of the crystal with the analyzer and when you get in close proximity to the frequency, you will see the SWR meter needle start to do a rapid dance. You are very close, Then very slowly tune for lowest steady SWR and the display will lock on to the crystal frequency as shown on the display.

All of my TR4C crystals read exactly on frequency except for the 21.5mhz which was off by .001mhz. All are fine to use.

You can skip the resistor but it is much harder to find the "dip" in SWR. One bit of advice, if the unit has not been used for a while just spin the tune dial and band switch a few times because those are mechanical switches/pots on the analyzer.

Good luck and 73, Dick KF4NS

Some think it really makes no difference. I've aligned
both ways and I didn't notice much. Its easy to slip and it
can burn up a resistor.

Hi George,

Tell me a couple of things:

1) How many rows of cooling vents are in the top and bottom of the cover?

2) Does it have a factory-installed 3-wire power cord or a two-wire cord?

I'm in Loudoun County, so pick-up is definitely an option.

Two rows of vents with two sets of vents in each row . No vents on top.
AC cable is two-wire. I have not upgraded this AC4. I actually have two
AC4s available. One is S/N 51xxx and the other is S/N 54xxx. I am
reducing my Drake "inventory" . Plan to keep my best C line and one L4B,
I live in Stafford and would be glad to meet you about halfway which I
guess would be Manassas... Let me know if you are interested.

From: Don Cunningham
Topic: 4487 Message: 4489

Craig,
I have one of those with a different problem. The AC supply and rig fan is on ALL the time, while the rig switches on/off normally. Those switches are "unobtainium", unless you have a parts unit or someone has been hoarding them and has not said anything!! I guess we need to figure out how to wire them for continuous on of all functions and use a power strip to do the acutal work.
73,
Don, WB5HAK

Date: 2010-10-16 15:19:42 UTC
From: Don Cunningham
Topic: 4482 Message: 4490

Can anyone shed any light on what the AC-4 power supplies are bringing?? I may rebuild with the AC4R a couple of "parts carcasses" that I have kept for years and use them with my gear. That may leave me with a couple of untouched, good condition supplies that are actually spare. If they are only bringing $50 to $75, I think I will just keep them for the spare transformers they would provide. Transformers even rewound would likely be more than the "bringing price" of the AC-4. Any thoughts?? Also, in your junk, would any of you have the bottom cover for an AC-4 that you would sell?? One of my "carcasses" is missing the bottom cover.
Thanks,
Don, WB5HAK

Which is why I leave mine on 'all the time", and use an external
switched power strip.

Some have claimed to have opened the switch and cleaned the contacts,
but ....

Bob -

Just don't do it! Consensus over the years is that it is not
necessary. The idea is to 'detune' the 'other' winding during alignment
to avoid interaction. Much easier and just as effective to just go back
and forth over the two adjustments a couple of times, and a LOT safer
for the radio and you.

From: Craig Roberts
Topic: 4495 Message: 4495

Well, it wasn't the power switch after all. It was a dirty "STORE" switch (the useless orphan one I neglected during my "out of the mothballs" DeoxIT spritzing spree). Nevertheless, I've put my rig on a handy, separate switched outlet so I won't have to exercise the aging power switch. I had done this with my old Collins gear, but had thought of the TR7 as being my "new" rig. :-)

73, fellas.

FOR SALE: Box of Cinch-Jones Connectors

Approximately 90 pieces, everywhere from 2-pins to 15 pins.
Some are cable-end types, others are chassis mount. Many are
in pairs (M-F) - many of these parts are new, several are used, but all
are in great shape, and they come in very handy around the ham shack.

Will sell the entire box for $40.00 plus $12.00 for USA shipping.

73 - Brian, AF4K

Date: 2010-10-18 09:47:33 UTC
From: Victor
Topic: 4499 Message: 4499

Hi all
Have a faulty T4XC following a magnificent display of magic smoke associated with the EHT. Replaced the cooked components but now no transmit.
Have been doing a resistance check and so far odd results. On pin 7 of V's 2, 3 and 7 the handbook chart shows a reading of infinity but on all of the tubes I get a reading of 9meg.
Any ideas, please?

Vic

Vic -

Those are the cathodes of the three stages and are used to key the transmitter. A single contact on the relay grounds them for transmit.

First, be sure the switches are set as described in the Resistance chart. If those are correct, then you may have a leaky switch wafer, as that lead goes through several switch sections.

You say 'no transmit'. Do you have bias current in TUNE or PTT closed? Can you hear the low level signal in the receiver?

Gary
Will come back to you on that. I had the correct EHT and standing current but the standing current has now gone. Also, and here's an odd
ball, if I turn the pre-select anti clockwise the meter lamp goes out - turn it clockwise and it comes back on !! No dimming in between
just on/off. I appreciate that the pre-select control is just about immediately in front of the meter lamp and if I had a bad contact on
the lamp holder that a bit of movement may make/break the cct but that isn't the case the lamp is definitely being switched by the pre-
select.

Interesting that you should mention the relay, I have just changed that. I took the relay from my other T4XC (which works fine) and tried
it in the duff one = still no good.

Am going to do a bit more fiddling and measuring and see what happens.

In my distant memory I seem to recall that you once said ' this is fun!!'

Cheers, Gary

Vic

Vic -

Ahhh, the plot thickens..... Losing the BIAS current ALSO says that the 'transmit' (Pin 7 of V2, 3 and 7) bus is NOT being grounded by the relay. These pins, AND the return for the PA cathodes are all grounded by a single relay contact. So you're looking in the right area. You can try just grounding any of those Pin 7's in TUNE mode and see if you then get idle current and output if you increase the GAIN control. Check the ground connection on the relay board.

I suspect your meter lamp problem is that the Preselector rack is shorting out the bulb. It's not blowing the fuse, because the bulbs in the T-4XC are each driven from 12 VAC via a 39 ohm, 2W resistor. It won't do that resistor any good! :-) These resistors are on Board 6.

"We do this for fun ..." "We do this for fun ..."

Garey,
I have met the enemy, and it was me!!! I think I got it finally, this time around. I took my "working T4XB" and put it through your proceedure. Worked just like advertised and I could hear good results in a monitor receiver. Then I tried the "non-working" T4XB (I cheated and put C2 about where the working one came out). The rig only required minimal touchup of C2 to get it balanced, and it sounds MUCH better on the monitor receiver. I'll try it tonight on the air and get some reports. Sure wish some of you guys were around to give me some on air checks!!!!!!!! And, no, I haven't been outside yet, Garey. I just can't clear the mind till something is fixed, hi.

Hey, whatever works! :-)

On some transmitters it is possible to get the CO on the 'outside' of
the filters instead of 'between' them. Should be real close to 5.645 MHz.

Well, I guess, although I am retired, I need to keep a calendar. I had forgotten yet another committment I need to make and may not make it back by 0100. Please, any of you that can make it, go ahead without me. I will join in if we make it back in time.

My original need was asking a Drakester to help me check out the audio on a set of Drake B twins that I had recieved a week ago. I had been getting "high pitched, no lows, pinched audio" reports, but wanted someone used to tuning in signals to give a listen. I find that MANY of the hams nowadays expect you to be absolutely on frequency, and will even chastise you if you are not on an even 0 or 5!!!! Oh well, anyway, I wanted someone who actually could tune to a calling station, hi. After doing the carrier oscillator adjustment a couple of times, with a couple of different methods, I have pretty well decided that one or both of the the crystal filters is defective, causing the bad audio reports. I didn't want to subject all of you to that bad sound, so had put the C Line back on line for the sked. My wife saw Kris' message and asked me what time 0100 to 0200 tonight was, and told me I wouldn't be here likely :-(. Since this has kind of taken on a life of its own, please meet if you can and enjoy each other's company. I will try again Wednesday night at the same time, same frequency, so you can try two nights in a row if you like.

I have found set of filters a nice ham has given me the option to try, then pay if they work!! May be able to bring the old girl back to life after all. I probably would have "canabalized" the other T4XB if I had to, as this set of twins has the nicest copper I have EVER seen on one, and I've owned these off and on since about 1976 or so!!! Anyway, thanks to the group for all your support. I'll keep you posted on results. Garey has given me a test method for filters off line, and I'll give that a try so I can look at all of these ways of fixing my rig.
73,
Don, WB5HAK

Not at all, Larry, did I do that?? I just told Kris where I had been hanging out, sorry about that. This started innocently, asking for help from some ONE on here and has kind of taken on its own life, hi. Sure, let's move it up some, Kris, how about 7180 or so if there isn't a DX net or something there. I've been running into that stuff higher, that's why I went down some. I really don't pay attention to that "extra" stuff, since I'm an old, ancient Advanced class, hi. I do have to watch 80m as I can get into trouble there and not realize it. If that's not a good frequency, name one and I'll be there Wednesday. Hope you all enjoy tonight.
73,
Don

The idea is to be on 7.165 MHz from 0100 UTC until 0200 UTC.

If that FRQ is busy, then the first arivals should try to stay close. Later arrivals will have to listen carefully and jump in.

Don has a few Mics to try too.

Let's see what propagation brings to us. :>)

<GRIN> Hi Kris!

You never know how this stuff is handled. It would not have been surprising at all to see the activity totally focused on Advanced and Extras. That's what has happened with the Digi-SSTV and the likes of EasyPal - other than 14.233, the Digi-SSTV mode is strictly under the influences of the Advanced Ham.

I was beginning to think that this would be the case for the "Twis" night since no one raised the question regarding the frequency.

Anyway, all's well. Hope the idea takes root.

Many Regards,

Howard W6IDS

In the first place, Kris is NOT responsible for suggesting the frequency, it was me. I looked for several nights, not finding a really clear frequency EXCEPT that one that is where I have been operating lately. I have been an Advanced class ham since 1972 or 73, really don't remember now, but I only look on the charts as to where I can operate, and don't pay much attention to the rest, unfortunately, I guess.. I don't knowingly "discriminate" , but just mentioned casually to Kris that we try that frequency since it had been relatively clear for a few nights. From that, since the reply to is to the list, this simple meeting of two hams has grown. My apologies for the frequency chosen, but I bet you will be stepping on long established net toes in the 7180 to 7200 range!!!! I sure found it so, but heck, let's try. Dust off the old rigs and have fun. No limitations were intended by me, I just wanted to try out a few microphones I have sitting around and use the one that works the best originally with my B line, now the C line, hi.

For the moment I will not say much, just a request before anything further. I am trying to keep my cool.

Would someone please try something for me on a good working TR4C?

Connect a dummy load, no mic no key plugged in.
Set the VFO for 14.260mhz and tune up for max power out as read on a decent wattmeter (not relative power on the S meter).
Use the X-CW mode and SIDEBAND X.

Then let me know the XMIT GAIN clock position, the PLATE, RF TUNE and LOAD numerical knob setting, output watts and plate current.

I am trying to maintain my sanity but not sure how long I can last.
Enough for now.

Ok Dick,

On my TR-4Cw, here are the facts and figures:

Connected a dummy load (used the Drake 300 W job), no mic no key plugged in.
Set the VFO for 14.260mhz and tune up for max power out as read on a
decent wattmeter (Drake MN-2000 used).
Use the X-CW mode and SIDEBAND X -Yes.

Then let me know:
XMIT GAIN clock position, = 9:45
the PLATE = 7.1
RF TUNE = 6.2
LOAD numerical knob setting = 2.5
output watts = 110 (not as high as I'd like it but as much as I get on this band)
plate current = 4.2

I hope that helps,

Kris KM2KM

From: Dick KF4NS
Topic: 4538 Message: 4538

Ok Bill and Doug,
Thanks for your replies. My readings were similar; Xmit gain 9:30,
plate 7, load 3, RF tune 6,
output 150 watts, current 450.

Looks like I may not have fallen into the s*&% again. At first it was
back to it's old ways and was showing 600ma plate current with all
controls full ccw except for sideband switch at X. This occured right
after a repeat neutralization using my scope. I will not say this time
that I FIXED IT I FIXED IT because I will wait and see.

I also went over the band switch wafers again and pressed on every
contact, using a high magnifier and made sure all were actually
lifting up when the contacts made. A couple were iffy. I did a good
cleaning and put Deoxit on the rotating discs.

In my 72 years I have eaten lots of crow but it never tasted so bad as
this, when the plate current shot up.
Wish me luck and maybe my nightmare is over.

Kris,
Thanks for the try, but I didn't hear you or Bob or anyone talking about Drakes. I did hear a W1 working a WD5 mobile station, the Ole Miss net and some activity above 7.190. Sorry we couldn't make the trip to New York for some reason. I have been hearing New Jersey stations this past week, so maybe we can do it another time. I hope you found some stations to talk to with the old Drakes.

Bill,

That was probably me tuning up my B-Line and L4B hi hi.

I heard Kris talking to a station in MO but had to leave for about 15 minutes. When I came back, Kris and the other station were gone.

Oh well The Drake Net on 7.238 (Sunday□s at 2000 UTC) is not a bad place to talk about our wonderful Drake rigs.

4547. Drake TR7 help needed

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-24 14:52:15 UTC
From: kf0hr
Topic: 4547 Message: 4547

Hello Drake list,

Picked up TR7 last month. It works very good on TX and RX. I am impressed with the receiver!

It has a couple things I would like to correct.

First - the PTO or VFO makes a rattle sound when I spin the knob at a fast rate.

Second ☐ AM audio is so narrow, anyone tried the home brew wide filter or just get the 6KC filter and be done?

Last ☐ My digital display is off frequency on all bands all the time?
It always shows 300 cycles high when I tune into a station on 3.937 it shows 3.937.3 Mhz.
Same on WWV 10.000.0 Mhz zero beats to 10.000.3
Most new rigs with read out has made the operating on even frequency.
3.900 or 3.905 well my TR7 would have to be tuned to 3.900.300 or 3.905.300 to sound on frequency.
The hundred herts digit on the TR7 Display does change as I tune the VFO.

Thanks for the band width,
Teran KF0HR in North Dakota

Hi Teran,

Congrats on the "new" TR-7. Comments inserted below.

On Sun, 24 Oct 2010 14:52:15 -0000, kf0hr wrote:

> First - the PTO or VFO makes a rattle sound when I spin the knob at a fast rate.

It sounds like the nylon gears are rattling, I've seen this happen. You could tear down the PTO and re-lube it, but that's a major job. Genereally, the nylon gears don't require any lubrication, but I have seen it in some. You need to be careful of the kind of lube you use on the gears, as some types will swell the gears and yo will have another problem. I've used TriFlow bicycle grease, it seems to work OK. Some of the gurus maintain the NO grease or oil at all should be used on the nylon parts. What is probably more likely is that dried or stiff lubricant on the parts of the PTO drive that are supposed to be lubricated is aggravating the gear rattle.

> Second ☐ AM audio is so narrow, anyone tried the home brew wide filter or just get the 6KC filter and be done?

That's nornal when listening to AM through the stock 2.4 KHz SSB filter. You could go with an AM filter, they used to show up reasonably priced on the auction site, but recently seem to have gone up a little. The Drake factory mod of placing a resistor across an unused filter slot works fairly well, it effectively gives you an AM bandwidth of 8 to 12 KHz, depending on your first IF roofing filter. Not optimal, but it works and it's cheaper than buying an actual AM filter. One note, if you do get an AM filter, the rig can be modified to use that filter on transmit as well, which gives you full bandwidth double-sideband AM on transmit. With the standard configuration, you actually only transmit one sideband with carrier on AM.

> Last ☐ My digital display is off frequency on all bands all the time?

Your rig needs to have the crystal oscillators aligned to frequency. It's not a difficult task, but you need an accurate and sensitive frequency counter to do it properly. Unlike modern rigs which use PLL oscillators under computer control, the digital readout of the TR-7 is an actual frequency counter sampling the analog PTO output. Any error on the frequency of the crystal oscillators in the radio will show up as frequency error on the display. Full alignment info is available in the service manual, which can be found on the internet for free download at a couple of the usual sources.

For more information than you probably ever wanted to know, you may also want to surf the Drakelist archives available at http://www.zerobeat.net/drakelist/ , and also visit the wb4hfn.com web site.

I hope this helps.

Hi Gary.
Sorry for delay in answering but had grandkids all week - 3 & 6 and a handful!
Still haven't got this going. To refresh your overburdened memory I had a bit of a burn out from the EHT. Replaced the cooked bits and no IC and then lost standing current. Messed with the relay and now have standing current but no RF out.Did as you suggested and tried grounding pin 7 on the appropriate tubes - still no output.
Have, so far, checked the voltages on the PA's, driver and mixer and they are within reasonable range.
It may help if I tell you how my problems came about. It worked fine but needed neutralizing. The only way I know is to stand the rig on its side and adjust from underneath. During that process R38 started to burn and arc to earth. Switched off quickly and did a physical check around. R38 seemed to be the only casualty. Stupidly I replaced that and switched back on. For a few seconds all seemed fine until the driver warmed up and started conducting and then it cooked R44 (680) and charred some of the wiring also.
Further inspection showed that board 6 (on your CD) didn't look very heathy. So far I have totally renewed all of board 6 except the tubular ceramic, replaced R38 &R44 etc.
I think what happened was whilst I was neutralizing (the rig on its side) one of the PA's shorted internally but I also noted that the leads from the fixed cermaic across the neut. cap were too close for comfort and whilst adjusting the rotor touched the wrong side of that cap Not sure but a possibility.
So that's how it stands at the moment. Sometimes I feel that I am within 1" of getting it sorted but the next day it somehow extends to a mile!
Cheers
Vic

4550. Lookoing for a 19" Rack for a DRAKE RR-1

Vic -

OK. Well, first, I think the R38 problem may have been caused by standing the rig on it's side! I assume you stood it on the LEFT side, i.e., trimmer caps on the bottom. I suspect either a wire clipping, solder splash, or ... managed to short one of the GRID (Driver) trim caps to the chassis. This WILL smoke R38, as it is then connected through R39 directly across the +250 VDC bus. I would imagine that R39 is also much the worse for wear.

R44, interestingly, is subject to the same problem, being subjected to the same treatment from a short from any of the PLATE (Driver) trim caps to the chassis. These problems, by the way, are the reason you DO NOT use a metal screwdriver to adjust these trimmers! :-) OR, since you say the neutralization cap was shorted momentarily, THIS will put 650 VDC on one side of R44 with +250 VDC on the other and would also severely overload (235 Watts!) that 1/2W resistor. :-) This short would also apply 650 VDC through T7 to the plate of V4. It's possible that T7 has broken down internally with a shorted turn(s).

If you do not have a scope available, I would try tuning up on 15M and listening to the signal on a receiver. See if you have ANY signal, and if you do, does T7 'peak' normally.

Grounding Pin 7(s) will only get you the idle (standing) current.

I assume you have tried another 12BY7.

4554. 4 B Line Dial

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-27 01:24:36 UTC
From: Don Cunningham
Topic: 4554 Message: 4554

In the purchase of a nice R4B/T4XB set recently I got a mint, unused dial for the 4 B Line Drakes. Was there someone looking for an unblemished one as a pattern to reproduce them?? If so, I would send this one only asking that it be returned and that I get one of the reproductions for my parts bin
so I could replace mine in the future. Am I remembering right, or just wishful thinking, hi.
73,
Don, WB5HAK

4555. Early model of TR7 and R7-possible improvements

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-27 04:47:51 UTC
From: Wojciech
Topic: 4555 Message: 4555

Hello group,
I own a very early version of TR7/R7 (serial numbers around 700)
Is someone aware of possible modifications to these radios introduced by R L Drake in their subsequent series? Especially my R7 seems to be very deaf in comparison to TR7.

All details would be appreciated-

Tom, VK2OE

Don:
You hit Gold.
You may want to scan your dial into your computer and print the results out on some clear transparency for a backup. The exact size transparency can also be used by someone to make the dial.

No mods that would affect sensitivity, that I know of.The R-7 should be as sensitive as the TR-7, as the RF strips are vritually identical. Could be dirty/oxidized bandswitch or PCB Molex connectors, a fault in the antenna splitter/switch, or maybe the first mixer brick is bad. Don't overlook the possibility of an overstressed RCA jack as well.

There were some mods to the 2nd IF/Audio board in the TR-7, but nothing that would alter the sensitivity. You can find some of those detailed here:

http://radiojim.exofire.net/pages/TR7_2IFA.html

4558. Copper Chassis?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-28 23:09:17 UTC
From: Bob Macklin
Topic: 4558 Message: 4558

Did Drake put an overcoat on the copper plated chassis? Or was it uncoated copper?

Bob
It is copper clad steel with a protective lacquer type finish
Pinholes in the plating lead to rust just like a cadmium plated steel
chassis
The lacquer also deteriorates with age and heat, comes off if you get too
agressive cleaning it

From: Bob Macklin
Topic: 4558 Message: 4560

I ask the question because I have a Heath HR-10 chassis where the CAD plating is flaking off. Do I want to try and get it replated or just paint it? If I pint it I will have to mask or clean off spots where a ground is required.

I asked this question because I have heard of other painting chassis.

I don't think you will be able to get anything cadmium
plated these days, its considered a serious environmental
hazard right along with mercury.
Painting the chassis with an anti-rust paint may help.
You will have to either clean the paint off or use star
washers where gounds are needed.

Bob
I have had good success (IMHO) on my older Drake gear by first a careful cleaning with warm soapy water applied with toothbrush and Q tips.
Carefully rinse with clean clear water, blot dry.
Then I begin cleaning and polishing with MeGuires paste wax with cleaner
I work it around good with an old tooth brush and Q tips, let dry and begin polishing with Q tips and soft rag pushed about with the handle of the tooth brush.
Takes me several sessions over a couple evenings to do a 2B. Sessions are always accompanied by 75m rag chew and enjoying favorite fermented beverage
The cleaner agent (possibly ammonia) in the polish seems to pull much of the corrosion out through the lacquer and the polish is a protective coating to the lacquer. They look pretty darn good in the end. Maybe it's the beverage hihi.
Works for me. YMMV

Paul,
Mequires makes several "polishes". Can you specify a number, or distinctive kind of polish?? I have a nice R4B with the best chassis I have seen, and I'd like to protect it. The T4XB that came with it is nice, but it is starting to have the pinholes and even some dime sized areas in a couple of places that need some attention. Thanks!

Paul,

Ditto here. I have a late serial number B-Line with only a couple of spots/pin holes on the R4B chassis and none on the T4XB. I also think there's an article on the WB4HFN website about reconditioning the copper chassis's.

Also, the worst thing you can do is touch the chassis with your fingers/hands. The oil from your hands (along with heat) will start the oxidation process and over time is probably the main reason for a lot of the pitting.

Best Regards,

Don
It is an oldie (like the radios)
All it says on the can is Meguires Cleaner Wax-clear coat safe---America's top selling A-1214
Has a very pronounced ammonia odor when opened. Gives me a headache after a while.
I did my 2B, R4, started my T4X and several others. Also trying it on a cadmium plated chassis on a linear and that is proving to be quite a chore getting an even lustre. The Drakes were easier possibly because of the laquer finish.

If the Drake chassis does have a lacquer overcoat you sure don't want to use anything like lacquer thinner or acetone for cleaning.

On my Heath HR-10 chassis I use 409 and all the lettering came off!

What ever you do cleaning some of the stuff is sometime surprising. Some Heath panels are not bothered by lacquer thinner but other are. How do I know? GUESS!

Some lacquers and some inks are dissolved by a medium
strong alkaline solution. Many cleaners are quite alkaline.

I recently bought a Heath IP-27 power supply off eBay. It has silver overspray on the front panel. I tried cleaning it with enamel thinner and it damaged the lettering. So I removed it all and redid it.

A couple of weeks ago I wanted to remove the lettering from a Heath HM-15 SWR meter case. Nothing I had would touch it.

It seems you just cannot tell what will happen.

What are the feelings about painting an old chassis. This is not a restoration. Jut to make it useable.

Some lacquers and some inks are dissolved by a medium
strong alkaline solution. Many cleaners are quite alkaline.

Bob,
I would think you are doing the right thing to paint one that would likely be stripped of parts and just discarded!! I see far too much of that from some sources!! I, for one, would rather see this gear used. Of course, final disposition is always up to the owner, not me, hi.

From: billykatzz
Topic: 4575 Message: 4575

I'm currently using a 40 meter, twinlead-fed dipole with a 4:1 air core balun connecting to my MN4 tuner. A month or two ago, I tried tuning up on 80 and was pleasantly surprised that the rig and tuner had no problem matching to the dipole.

Last night, I tried getting on 80 again, but this time I couldn't bring the tuner adjustment down. I'm not sure what changed. Shouldn't the MN4 should be able to match the antenna? What gives?

Bill,
That's a pretty good stretch for a tuner. Sometimes it will fool you and at least show a match, but in most cases, you are just fooling yourself. Now a twinlead-fed 80m should tune on 40m. You just need more wire, like half wave on the lowest frequency you will use. My 160m will, with some fiddling, tune up to 20m okay, but 80m dipoles will just not work on 160m.

Bill,

Are you sure you had all the settings the same? If so, try a small amount of DeOxit on the switches in case one of them isn□t low resistance.

4580. Re: [DrakeRadio] T-4XC

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-10-30 09:22:44 UTC
From: g4jss@tiscali.co.uk
Topic: 606 Message: 4580

Hello again Gary
Still no further forward.
Didn't use a metal screw driver -frightened to death of EHT!
I tried tuning on 15m but no signal of any kind on a Rx. Again changed all the tubes (including 12by7) from a working T-4XC but still
the same.
There is an oddity - I
disconnected the fixed ceramic across the neut cap and on 20m I got IC and the watt meter read what appeared to be RF out. The peak on the
pre-select was very sharp - almost critical. Somehow I think this was a false reading because the readings showed that I was getting 100w
out with little or no gain applied! This only happened on 20m nothing on the other bands.

Re T7, I do have another T-4XC chassis complete with pre-select tuning rack and T's. I have had a good look but it beats me how I am going
to get that out. Is it as difficult as it looks or is there an easy way, please?

Cheers

Vic

4581. Testing the AC-4R upgrade

Yahoo group: DrakeRadio (2006 — 2011)

Hello Everyone,

I completed re-building my AC-4 power supply with the upgrade kit. I am at the point were I need to test it prior to plugging it into the Drake radio. The instructions say "On the large connector, those two pins are #1 and #2. You can use a short piece of insulated hook up wire to short the two pins together."

Question: I do not understand what is meant by "... those two pins"
The instructions refer to the 12-Pin Cinch Jones Molex connector (correct?)but which are pins #1 and #2. I did a little searching but didn't find an answer. Tnx in Advance!!

The AC-4 manual shows the layout of the power connector. But I would suggest using your ohm meter to identify the proper pins.

When I did mine I used a clip lead across the terminals inside the unit.

Many years ago I bought my Benton Harbor S-Line twins from a person that had switched to Drake Twins. I bought my Drake Twins the 1st of this year. I have found out why he switched.

My Benton Harbor S-Line twins are not bad. In some respects easier to operate than the Drake twins. But I can here people on the Drake twins that I cannot find on the BH twins.

Hi Don & all,

Since you mentioned Hamfest are legal to post here please be aware of one of the midwest finer hamfest coming up next Sunday 07 November 2010.

My home club, The Davenport, (Iowa) Radio Amateur Club (DRAC) is holding it's annual hamfest at the Clarion Hotel 5202 North Brady Street on the S.W. Corner of U.S. 61 Northbound and East 53rd Street. Davenport, Iowa GPS Coordinates are N 41 34.413 and W 90.34.197

You can usually count on some Drake TR-4 radios, and somtimes earlier models..

I have been living in the bush of Alaska for about the last two years and am heading home. Not sure of my flight date yet so I'm not sure if I'll be there or not. If I'm home I'll be there.

Oh, I almost forgot, the club home page is: http://www.arcsupport.com/drac/ There is a link there to the hamfest flyer.

73,

Dave, N0TXJ

4588. general question on microphones

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-01 17:01:18 UTC
From: William Houghton
Topic: 4588 Message: 4588

Hi fellow Drakies,

My question today is a general one on mics stemming from bring to life a non-Drake radio (gasp). However it is related to the Drake family in that the person who designed the Heathkit SB-104A is said to have later gone to Drake and designed the TR7. Hopefully he eliminated the 'birdies' that the '104 is well know for.

My question is about mics. How much output on voice peaks would you expect to see on a scope at normal speech levels? I realize that a pretty open ended question. My SB-104A seems to be working well now except that it seems to take about 150mV of audio at the mic input to drive it to full output. The troubleshooting/checkout section of the Heath manual says to feed a 150mVp-p 1KHz signal into the input and measure the signal levels at the inputs and outputs of the mic amp stages. Mine are fine with 150mV and that 150mV signal does drive the rig to full output as measured on a W-4 with a dummy load.

It does seem to me that 150mVp-p is a really high output requirement for a mic (about -16.5dB ref to 1V). That even seems like a high output for an amplified mic based on some specs I have seen for mics. I bought this radio because my community college had one back when I first got licensed. It was the first SSB station I ever operated. I don't remember the mic that was bought with it from Heathkit as being an amplified mic, but I could be wrong.

How much output do you see from your mics? Is there any flaws in my thinking ?

73,

WA6NEQ (Bill)

Sounds high to me too. The highest output non-amplified
mic I know of is the Astatic D-104 which is rated at -45db
below 1 volt per microbar sound pressure. This is a very old
standard for high impedance mics. A microbar is equivalent
to 10 dynes/cm^2, now stated in Pascals. This pressure was
chosen because it is an average of the peak pressure of male
speech at one foot. Most microphones are around 10db lower
than the D-104.
I just measured the output of four microphones using a
scope. The mics were:
Astatic D-104
Electro-Voice 635 dynamic on a matching transformer
Electro-Voice 602-D close talking mic.
Shure 55S cardioid dyamic
The 602-D, which is used right against the mouth puts out
over a volt but the others don't come close. The D-104 is
the next highest with about 60mv P-P at around 8 inches but
much more when used close.
The Heath spec is probably for RMS voltage and I am
looking at peak-to-peak. The close-talking EV mic is the
only one that would put out enough.
An amplified mic should easily meet the requirements of
the TX but perhaps it was intended to be used with a close
talking mic of some sort.

Hi Richard,

I measured my D-104 unamplified at about 50mVp-p depending on distance from the mouth. I also looked back at the Heath specs in the Ops manual and found that Heathkit specs the mic requirements as -45db to -55dB @1KHz, Z = 25K, about 1.6 to 1.8mV. (hmmm is 0dB for a mic 1Vrms or 1Vp-p ?). This suggests that it should be pretty easy though to drive the audio from most unamplified mics.

I'm wondering now if the 150mVp-p bench test was chosen because it is relatively easy to get at the lab bench whereas 1.5mV might be more difficult for the average ham to do (back in 1977) ?

I might be taking a look at the ALC circuit soon, hmmmm.

73, Bill

Sounds high to me too. The highest output non-amplified
mic I know of is the Astatic D-104 which is rated at -45db
below 1 volt per microbar sound pressure. This is a very old
standard for high impedance mics. A microbar is equivalent
to 10 dynes/cm^2, now stated in Pascals. This pressure was
chosen because it is an average of the peak pressure of male
speech at one foot. Most microphones are around 10db lower
than the D-104.
I just measured the output of four microphones using a
scope. The mics were:
Astatic D-104
Electro-Voice 635 dynamic on a matching transformer
Electro-Voice 602-D close talking mic.
Shure 55S cardioid dyamic
The 602-D, which is used right against the mouth puts out
over a volt but the others don't come close. The D-104 is
the next highest with about 60mv P-P at around 8 inches but
much more when used close.
The Heath spec is probably for RMS voltage and I am

looking at peak-to-peak. The close-talking EV mic is the
only one that would put out enough.
An amplified mic should easily meet the requirements of
the TX but perhaps it was intended to be used with a close
talking mic of some sort.

4591. Add-on ALC indicator?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-02 00:48:25 UTC
From: Gary
Topic: 4591 Message: 4591

All this talk about microphone levels reminded me of another
question...
Since the Drakes don't have an ALC level indicator or metering,
has anyone come up with a good modification for one? I seem
to remember something about an LED mod in the distant past.

73 and TIA,
Gary

Subject: Re: [DrakeRadio] general question on microphones

Hi Richard,

I measured my D-104 unamplified at about 50mVp-p depending
on distance from the
mouth. I also looked back at the Heath specs in the Ops
manual and found that
Heathkit specs the mic requirements as -45db to -55dB @1KHz,
Z = 25K, about 1.6
to 1.8mV. (hmmm is 0dB for a mic 1Vrms or 1Vp-p ?). This
suggests that it
should be pretty easy though to drive the audio from most
unamplified mics.

I'm wondering now if the 150mVp-p bench test was chosen
because it is relatively
easy to get at the lab bench whereas 1.5mV might be more
difficult for the
average ham to do (back in 1977) ?

I might be taking a look at the ALC circuit soon, hmmmm.

73, Bill

The standard for microphone levels is for RMS. Where it
mentions peak that is the peak of the speech envelope. The
standard for years has been 10 dynes/cm^2, approximately
equal to a SPL of 94db stated as a power level in dB with
reference to zero being 1 mw in 600 ohms (i.e.. dbm). This
is common for low impedance microphones. High impedance
microphone are often referenced to 1 volt and old references
were often to an acoustic level of one "bar" or sometimes
ten "bars" here bars really meaning microbars. Its possible
to translate one to the other but it takes a lot of
calculation. Typical low impedance dynamic microphones
have an output level in the vicinity of -55 dbm for a force
of 10 dyne/cm^2. High output crystal mics can be as much as
10db higher. The use of a power level reference makes sense
because it is independent of the impedance. Most microphones
are designed to work into an open circuit regardless of the
rated impedance. Microphones with amplifiers of some sort,

including electret and condenser types may be exceptions
although they may also be designed to work into an open
circuit. Carbon microphones _are_ amplifiers so their
operating conditions are different.
As to the last point, generating type microphones
(crystal, moving coil dynamic, ribbon, magnetic) have about
the same output level now as they did seventy years ago.
What has changed is that many microphones now come with
built-in amplifiers, or electronic impedance matchers, and
modern solid state circuits can be designed to work directly
from low impedances without the matching transformers needed
by electron tube amplifiers.

Well, there is a jack on the side of the AC-4 supply
that carries the ALC voltage. Its meant for a linear
amplifier but a high impedance meter will read it and it
will show you when the ALC is working.

I thought that was an ALC INPUT.. cuts the T-4X drive
when the external linear goes non-linear.. no?
Oh, maybe you say it shows the internal T-4X ALC level unless
you over drive it with the linear signal..?

It is but its connected to the AVC buss in the T-4 so
that the AVC voltage appears on it. Put a high impedance
meter or scope on it and have a look.

4596. Re: general question on microphones

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-02 15:49:02 UTC
From: w8nf
Topic: 4588 Message: 4596

The actual output voltage of microphones is, of course, rather dynamic, since the human voice is dynamic. The Collins engineers who compiled the several books on SSB claim that an individual human talker, even when speaking in a monotone, had a dynamic range of about 35-40dB.

Two standards exist for specifying microphone output; one expecting that the mic will be used in sound reinforcement applications. This standard dates back to when all musical entertainment was live: no Memorex. Talking distances was one foot or more. The other standard, for communications, expects a close-talked microphone. Neither standard really accommodated the wide dynamics of the human voice.

I've been developing a speech processor for some time, and absolutely had to know the output voltages, as averages and peaks, so that I could properly design a mic preamp that could handle a wide range of microphones. Accordingly, I made measurements using my own voice.

D-104, crystal version: highest output mic. Up to 2Volts peak when speaking loudly into it. Also has the highest output impedance: I measured 5 MEGohms at 300Hz. This microphone's output voltage will decline rapidly due merely to cable capacitance. Astatic's original recommendation was to use no more than 3 feet of cable: even that short cable will drop the output voltage by half. The output Z is also highly capacitive: a 1Megohm load resistor will reduce the bass output more than the treble output, and will make it sound tinny. This is a difficult microphone to measure because the input Z of an oscilloscope loads it noticeably.

D-104, ceramic version: 500mV peak with a loud voice. Output Z measured 25k ohms from 300Hz to 5kHz, so it can handle a load better. Most D-104s in existence are of this variety.

EV638: 1V with a loud voice. This is a high-Z dynamic mic: I didn't actually measure the Z, but I noted that the output voltage declined slightly with a 10k load resistance.

Electret microphones (all stock Icom mics and most computer/PC gaming headsets): these require bias and have an internal buffer/amplifier. Typ 200mV output, but one measured a full volt. Lowest output Z of any mic, typically 10-20 ohms.

Large-diaphragm dynamic mics (Shure SM58, most studio mics): typ 30-50mV peak. Measured output Z is 150-200 ohms, designed to work into 500-5kohm inputs.

Small-diaphragm dyanmic mics (most Heil products): 10mV if you're lucky. You need good RFI-proofing to use a Heil, since you'll be using a mic preamp with a lot of gain.

For vintage rigs, you really want to use a vintage mic: if you use something modern, you'll have to get involved in some sort of interface circuitry.

Hope that helps...

Hi Dave,

Thanks for the reply. I'm going to save a copy because I think there is a lot of useful information. I have a D-104 but I don't know whether its the crystal or the ceramic element.

After I wrote my email, I did came across the Heathkit mic spec. Zin of the audio stage is 25K. Mic level should be -45dB to -55dB, about 1.5mV to 5.6mV. Most of the non-amplified vintage mics should be able to drive it.

There is a "marked up" schematic that Heathkit techs used for servicing the SB-104A out on the web. The schematic says to feed a 150mVp-p, 1KHz signal into the mic input and measure the input and output signals of the audio amp stages. Mine matches quite well the Heathkit notes. At 150mV on USB or LSB, the rig will drive to full power out. In my mind, this says the tx audio stage is probably okay.

I guess its on to the balanced modulator.

73,

Bill

Subject: [DrakeRadio] Re: general question on microphones

A couple of notes: 1, a great deal of research into the human voice and its characteristics exists in the scientific literature. The earliest work was probably that done by Bell Labs but there were many others. There are many sources, a good one to begin with is the _Journal of the Acoustical Society of America_ and a second is _Bell System Technical Journal_. Both have compresensive cumulative indexes and are not difficult to find.
Dynamic properly describes a microphone or loudspeaker which relies on a magnetic generator or motor for its operation. This includes such types as moving coil microphones, often called "dynamic", ribbon microphones, and magnetic microphones of both the variable reluctance and moving armature varieties. For the most part these have inherently low generator impedance and rely on transformers to increase the impedance to a useable level. Moving coil microphones typically have an impedance on the order of 20 to 50 ohms but higher impedance voice coils can be wound. They can be used directly into a matching transformer. Ribbon microphones have impdeances on the order of 10 ohms or less and invariably have an internal transformer. Magnetic microphones, like magnetic earphones, can be wound for high impedance directly but are more often like moving coil mics, that is they have an internal matching transformer.
All of these types are intended to be worked into an essentially high impedance because they are voltage sources and any load will reduce the output level. The usual vacuum tube microphone pre-amplifier used a matching voltage step-up transformer to feed the grid of a tube. While the input was specified to work from some low impedance, usually around 50 ohms or around 200 ohms, the actual load impedance presented to the microphone is on the order of several thousand ohms. It is the microphone which looks like the specified impedance. Ribbon microphones and some moving coil mics, particularly directional ones, have an impedance which varies with frequency usually having a peak at the low frequency resonance. The famous RCA 44BX, when connected as a 250 ohm mic has a resonant rise of around 2.5K at around

40hz. If worked into a resistive load the low frequency response will be affected. Normal pressure operated (non-directional) moving coil microphones have resistance controlled mechanical systems and so have constant approximately resistive electrical impedance. Their frequency response will not be significantly affected by loading but the output level will be reduced.
Crystal and ceramic microphones have extremely high output impedance and look like capacitors. Any load will affect both output level and frequency response. Usually, low end will be reduced. Cable capacitance will also affect both since it will act as a voltage divider with the internal capacitance of the microphone and also tend to reduce the high-frequency output.
In short, any generator microphone, whether it is a crystal, moving coil dynamic, ribbon, or magnetic, should be operated into essentially a high impedance even though a _voltage_ step up transformer is used. Condenser and electret microphones have an electronic amplifier associated with them and the load impedance is whatever the amplifier is designed for. These microphones are not generators but rather control an external source of voltage. In the case of the electret the element carries a permanent charge but is extremely high impedance like a crystal and is also similarly a capacitor so a matching device preferably located right at the element must be used.
Carbon microphones are rare these days but are also not generators. They are variable resistors which when used with an external source of power act as amplifiers. It is the amplification which made them so popular until electronic amplifiers became efficient and small enough to allow the use of electrets and other microphones in communication circuits. Even the best carbon microphones are noisy when compared to other types and have been supplanted in nearly all applications where they once dominated such as telephones.
A couple of after thoughts, the levels noted for the D-104 are considerably higher than my measurements. While my microphone is marked D-104 it is possible its actually has a C-104 (ceramic) element. While the output is higher than any other mic I have it is not quite as high as I would expect. The sound is OK and the impedance measures correctly so I don't think its damaged. When a crystal microphone goes bad its output drops substantially and the impedance becomes partially resistive.
Secondly, a correction: I think I stated that an old standard was 1 volt per bar per square inch. This is wrong, its per square centimeter. When the word _bar_ is used in these old specs it means _microbar_, a bar is equal to one atmosphere of pressure at sea level (nearly 15 lbs per

square foot).

Just got my new-to- me MN2700 tuner via fed ex.

The plastic shaft connecting the Resistive Cap knob to the Cap itself is broken, right where it enters this double-female piece that's wider (3/4") that holds the "knob shaft" (if you will) to the capacitor shaft --each held in place by a hex-set screw.

Any know an easy fix?

Crazy glue?

Must I take the whole thing apart?

Thanks in advance,

Brenton

4601. How to resurrect an old Drake

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-04 13:25:05 UTC
From: Larry Sack
Topic: 4601 Message: 4601

Hello All,

Just joined the list, and browsed some of the archived messages, looking for advice on how to bring a Drake TR-4 I inherited back alive. When I got it, it was open on the ham's workbench but it didn't look like it was being worked on. There are receipts where Drake worked on the unit in 1991 replacing finals and various parts.

So, what advice for testing, first powering it up after a long sleep, what to look for in bad parts? The power supply is a homebrew and I will be emphatic about this: I KNOW NOTHING ABOUT DRAKES! There, was that said loudly enough? I have two copies of the instruction manual and schematic, receipts of work done and a unique service document. That service document appears to be an internal Drake testing procedure complete with a technician's handwritten notes.

This may be a long road to bringing it back as I don't have alot of time to devout to this project. I just hate to see it sit another five years without being used. So, as I garner advice and support, I will try to keep the list updated.

So, what would you do with this rig? How would you go about powering it up again?

Thanks in advance for your advice in advance!

Larry, N8QNM

Larry -

If you do not have a manual, get one! This is a fairly complex piece of equipment, with multiple controls, that CAN be damaged or destroyed by maladjustment. Set the XMTR GAIN control full CCW, and the FUNCTION switch to SSB. Verify the slide switch on the left side of the cabinet is in the "towards the front" position.

Then I would check the power supply BEFORE connecting it to the transceiver. Verify that you have about 700 VDC, 250 - 300 VDC, 12.6 VAC, and most important, variable negative from about 50 to 100 VDC. Check the negative supply filter cap(s) for age and condition. If NOT _new-ish_ replace them. A negative (BIAS) supply failure can seriously damage the transceiver, even if left in STANDBY. Set BIAS adjustment to maximum negative voltage, which must be at least -75 VDC.

Check the three PA cathode resistors (15 ohm, 1W), the 68 ohm screen resistors and the meter shunt resistor (R45) for value and condition.

If all ok, apply power. If no smoke or other signs of distress (!) increase AF GAIN. You should hear background 'hiss', or if an antenna is connected, signals. If no hiss, verify that all tubes are lit (warm/hot). Just LOOK to see if PA tubes are lit!

IF all ok, turn XMTR GAIN control full CCW, FUNCTION switch to SSB, then while watching the PLATE meter turn the FUNCTION switch to X-CW. Adjust the BIAS voltage for 0.1 A of idle current. If unable to set to 0.1A, remove power and find out why! Do NOT allow plate meter to exceed 0.15A for more than a (very) few seconds.

If idle current can be set to 0.1A, then switch back to SSB.

Unless you are very familiar with tube type transmitters, do not proceed further without a manual. If further troubleshooting is required, keep in mind that there are eight (8) versions of the schematic over the years. While they are all functionally equivalent, there ARE differences.

Commercial message... IF you are going to work on / repair this unit yourself, you might want to consider my Service Supplement CD. It has all eight schematic versions, high resolution scans of the manual, and full color high resolution photographs of the under chassis with all parts identified and referenced to a parts list. Sample pages at my web site below.

Don't hesitate to post questions here on the reflector as you go. There is a wealth of information from some very experienced people available to you. You might also consider skimming through the message archives,

as most subjects have been covered! There is so much that it can be intimidating! :-)

FWIW, the peak to average ratio of male speech is at
least 10db. Where power is limited as it is in AM or SSB
transmission, a higher average can be gotten by applying
some compression or clipping or both. Also, the power
distribution in speech is not ideal for maximum articulation
especially where there is interfering noise. Most of the
power in speech is below about 1000 hz while it is the
frequencies above 1000 hz that mostly contribute to
articulation. Further, the power falls off with frequency
above about 1khz at about a 6db/octave rate. This is the
reason for the common practice of using microphones with a
rising frequency responce for communication purposes. Also,
transmitting frequencies much below about 1khz is wasteful
of power because there is little or no contribution to
articulation. Now, Bell Labs experiments conducted many
years ago, determined that while frequencies below 1khz did
not contribute to articulation they did result in
naturalness and telephone subscribers found circuits that
cut off at too high a frequency unacceptable. As a result
the telephone company set the low frequency cut-off at
around 250hz. For the high end the articulation falls off
slowly as the high limit is lowered from around 10khz until
it reaches around 2500hz below which it begins to fall off
more rapidly. If set at about 1 khz the articulation becomes
very poor. The 80 percent articulation point is around
2500hz and it increases to around 90 percent at about 3500
hz. Articulation with only a high pass filter is still close
to 90 percent with a 1 khz cut off.
So, for transmission of understandable speech through a
power limited medium its advantageous to limit the bandwidth
to around 300 to 3000 hz and to provide an additional high
pass filter of about 6db/octave over that whole range. It is
also advantageous to provide for some reduction of the peak

to average power ratio in speech. About 6db of clipping will make a substantial difference but more can be applied. Some sixty years ago Licklidder and his associates published a paper in the _Journal of the Acoustic Society of America_ showing that _infinite_ clipping could be applied to speech and still retain articulation at a very high level. The speech was first passed through a differentiator, then clipped, then passed through an integrator. The differentiator is a simple 6db/ocatave high pass filter and the integrator a simple 6db/octave low pass filter, the "cut off" frequencies of the low pass being above the range of interest and the high pass below the range of interest so that the curves applied to the entire spectrum. The articulation of such processed speech is less than unprocessed speech in the absense of noise but much better when noise is present.

The use of a compressor combined with a clipper can result in lower apparent distortion and greater naturalness of the processed speech while still yielding substantial power gain and improved articulation in the presense of noise. The compressor keeps the level into the clipper fairly constant so that less clipping can be used. The clipper essentially removes the short-term peaks while the compressor compensates for longer term variations. For practical use a "noise gate" can be added which limits the gain of the compressor so that it does not bring up background noise too much.

Note that the differentiator and integrator used around the clipper are in addition to any spectrum shaping filter used to compensate for the power distribution in the voice. This latter can be simply a microphone with rising frequency response or an additional filter where a flat frequency responce mic is used.

Note that there are many variations of clippers including those what work on a radio frequency envelope. The later may result in less dicernable distortion although they probably still have intermodulation distortion.

All processors introduce distortion, that is actually their purpose, but the naturalness or pleasantness of the output can vary a lot with the design.

A personal bug-a-boo, most broadcast stations, especially AM stations, use much more processing than has any benefit, they just sound bad.

There is a perfectly enormous amount of material about speech characteristics in the technical and scientific literature. I have not tried a web search but I have no doubt that anyone who is curious will find much more than they really wanted to know.

4605. Speech Processing (was general question on microphones)

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-04 22:35:30 UTC
From: Bob Macklin
Topic: 4605 Message: 4605

Richard Knoppow brings up good points about speech processing in communications.

The older ARRL handbooks have sections on this subject. I have built both tube and transistor speech processors. If you need a mike preamp you might just as well have a speech processor.

Look at the voice waveform on a scope. That big spike the is followed by a bunch of lower level waves is the primary problem. The spike can cause over modulation before the part carrying the intelligence is strong enough to be useable. The solution is to compress or clip it. The better speech processors allow you to adjust the clipping level according to band conditions. If you have a quiet band less clipping is required that when the bands are noisy.

Communications quality is not intended to be Hi-Fi!

Subject: [DrakeRadio] Speech Processing (was general question on microphones)

Richard Knoppow brings up good points about speech processing in communications.

The older ARRL handbooks have sections on this subject. I have built both tube and transistor speech processors. If you need a mike preamp you might just as well have a speech processor.

Look at the voice waveform on a scope. That big spike the is followed by a bunch

of lower level waves is the primary problem. The spike can cause over modulation

before the part carrying the intelligence is strong enough to be useable. The solution is to compress or clip it. The better speech processors allow you to adjust the clipping level according to band conditions. If you have a quiet band

less clipping is required that when the bands are noisy.

Communications quality is not intended to be Hi-Fi!

FWIW, the peak to average ratio of male speech is at
least 10db. Where power is limited as it is in AM or SSB
transmission, a higher average can be gotten by applying
some compression or clipping or both. Also, the power
distribution in speech is not ideal for maximum articulation
especially where there is interfering noise. Most of the
power in speech is below about 1000 hz while it is the
frequencies above 1000 hz that mostly contribute to
articulation. Further, the power falls off with frequency
above about 1khz at about a 6db/octave rate. This is the
reason for the common practice of using microphones with a
rising frequency responce for communication purposes. Also,
transmitting frequencies much below about 1khz is wasteful
of power because there is little or no contribution to
articulation. Now, Bell Labs experiments conducted many
years ago, determined that while frequencies below 1khz did
not contribute to articulation they did result in
naturalness and telephone subscribers found circuits that
cut off at too high a frequency unacceptable. As a result
the telephone company set the low frequency cut-off at
around 250hz. For the high end the articulation falls off
slowly as the high limit is lowered from around 10khz until
it reaches around 2500hz below which it begins to fall off
more rapidly. If set at about 1 khz the articulation becomes
very poor. The 80 percent articulation point is around
2500hz and it increases to around 90 percent at about 3500
hz. Articulation with only a high pass filter is still close

to 90 percent with a 1 khz cut off.
So, for transmission of understandable speech through a power limited medium its advantageous to limit the bandwidth to around 300 to 3000 hz and to provide an additional high pass filter of about 6db/octave over that whole range. It is also advantageous to provide for some reduction of the peak to average power ratio in speech. About 6db of clipping will make a substantial difference but more can be applied. Some sixty years ago Licklidder and his associates published a paper in the _Journal of the Acoustic Society of America_ showing that _infinite_ clipping could be applied to speech and still retain articulation at a very high level. The speech was first passed through a differentiator, then clipped, then passed through an integrator. The differentiator is a simple 6db/ocatave high pass filter and the integrator a simple 6db/octave low pass filter, the "cut off" frequencies of the low pass being above the range of interest and the high pass below the range of interest so that the curves applied to the entire spectrum. The articulation of such processed speech is less than unprocessed speech in the absense of noise but much better when noise is present.
The use of a compressor combined with a clipper can result in lower apparent distortion and greater naturalness of the processed speech while still yielding substantial power gain and improved articulation in the presense of noise. The compressor keeps the level into the clipper fairly constant so that less clipping can be used. The clipper essentially removes the short-term peaks while the compressor compensates for longer term variations. For practical use a "noise gate" can be added which limits the gain of the compressor so that it does not bring up background noise too much.
Note that the differentiator and integrator used around the clipper are in addition to any spectrum shaping filter used to compensate for the power distribution in the voice. This latter can be simply a microphone with rising frequency response or an additional filter where a flat frequency responce mic is used.
Note that there are many variations of clippers including those what work on a radio frequency envelope. The later may result in less dicernable distortion although they probably still have intermodulation distortion.
All processors introduce distortion, that is actually their purpose, but the naturalness or pleasantness of the output can vary a lot with the design.
A personal bug-a-boo, most broadcast stations, especially AM stations, use much more processing than has any benefit, they just sound bad.
There is a perfectly enormous amount of material about

speech characteristics in the technical and scientific literature. I have not tried a web search but I have no doubt that anyone who is curious will find much more than they really wanted to know.

or you can just get a KW amplifier -:)

Well, suppose the processing brings up the _average_ level ten db. That is possible with a combination of compression and clipping. That is the equivalent of increasing power ten times.

A speech processor. I had one back in the DARK AGES when tube radios were more common than solid state radios.

Should I include a "ROGER BEEP"?

I recently rescued a processor I built some forty years ago. Its was built from a design in an engineering magazine, I have no memory now of which. It is a sylabic rate compressor followed by a limiter. It still works (after chasing down a cold solder joint) and works on my Drake T-4XB. It probably sounds awful but does not seem to splatter and sure makes the power meter in the dummy load go up. I set the clipper for 6db using a scope. That's enough to take any overshoot off the compressor. I may still have the original magazine in storage but so much of that stuff got lost in moves that I don't count on it. The rig I used it on originally (but not much) was a combination of home brew and modified surplus with a Barker & Williamson SSB generator a friend gave me. It made very nice sounding SSB. I still have it. Perhaps one day I will find the B&W transmitter it went with. My friend originally drove it with a Collins 310B-2 and the generator drove a linear running a PL-172.

I run a "courtesy beep" on my 10 Meter mobile rig, becuase it came with the radio. It never ceases to amaze me how many hams will break the law by not IDing with their callsign when they try to harass me for doing something that is perfectly legal.

It might surpise some people to hear that the first "Roger Beep" circuit I ever saw was a construciton article in a ham magaizine. The author had designed it to sound exactly like the TX/RX changeover beeps on NASA astronaut transmissions.

4618. TR4C with RV-4

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-07 18:00:45 UTC
From: VE3FMC
Topic: 4618 Message: 4618

Ok this is a weird situation that started to occur yesterday.

I have a TR-4C which I use with a RV-4. Up until yesterday there was no issues with this setup.

However yesterday I turned both units on and I noticed I could tune into a QSO with the RV-4 set on the Transmit/Rcve setting. However if I moved the main tuning dial on the rig I could hear it tuning past other QSO's.

Now what would cause this problem to occur?

I took the RV-4 off the TR-4C this morning and hooked up the MS-4 and the rig is stable and works as it should.

Can anyone shed some light on this subject?

Thanks, 73, Rick VE3FMC

Rick -

Does the EXTERNAL PTO light on the front of the TR-4C come on?

If not, then possibly a dirty Pin 2 or a switching problem in the RV-4.
Much less likely R16 in the RV-4 has gone way up in value. The control
line is Pin 2 of the REMOTE connector, and it should be zero to enable
the PTO inside the TR-4C. A positive voltage from the RV-4 via Pin 2
disables the internal PTO.

If EXT PTO light does come on, most likely problem is a blown Q4 in the
TR-4C.

Thanks for the reply Garey.

That was the problem. When operating the RV-4 the VFO light on the TR-4C was ON.

I had moved the rig around yesterday. When I hooked the RV-4 back up today the VFO light went off when I turned on the RV-4 when I put the RV-4 in the RCV and RCV/XMT switch on.

When I moved the TR-4C back into the operating position on the desk the VFO light came back on when the RV-4 was on.

So I wiggled the VFO plug on the bottom of the rig and the light went out. So it was a bad connection on the pins of the VFO plug. Or a bad solder joint on the VFO plug. I will inspect the connections when I get a chance.

But for now everything is back to normal. I do not use this old rig often but when I fire it up I do enjoy talking on it on 40 meters.

Again Thanks for your help. That is why I joined this group because everyone is so helpful and most of you have a lot of knowledge about the old Drakes.

OK. The same control voltage (Pin 2) turns the EXT PTO light ON and the internal PTO OFF. So if that light doesn't go ON, the internal PTO is still running, resulting in your 'dual receive' situation!

The Cinch-Jones connectors are prone to corrosion on the 'blades', and this is a pretty low voltage point. Usually just plugging and unplugging a couple of times will scrape them clean. Some clean them with pencil erasers, but I just put a drop of DeoxIT on each side of each one and they seem to work 'forever'.

Glad you got it fixed!!

this same problem can occur with the T4XC and R4C combo if there is some fault in the INJ cable. there is a DC bias that facilitates control of the active PTO and a bad cable can cause these same issues.

I hesitate, but I should report that the low-capacitance cables I purchased from WB4HFN have been problematic and caused several related issues to surface. the cables have rather cheap RCA phono connectors with an odd plating that works poorly. making my own cables with high quality connectors and then alignment to match INJ levels solved all of the problems.

To RIck VE3FMC,

I have a TR-4 with a working RV-3. And what you are getting is what happens to me. When the RV-3 is set to any seeing that allows it to operate in receive mode, both the RV-3 and the TR-4 dial works.

I personally prefer this "feature", as it lets me monitor one frequency and look for another one simultaneously <grin>. But, lately, I have gone back to not using the RV-3 as I rarely have a great need to monitor two frequencies.

Have fun and good luck <grin>!

I could be talked out of mine; it's mint condition (I'm migrating to Icom), I just put in PEQ's LEDs to make the meters readable again. I would have to include the spare matched set of 500zs. stanley@... WA6LVC

All group memebers are welcome to post here on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others (what you put into this group you will get back so participate if you have a chance). Although we would like to focus on Drake Radio subject matter any Ham Radio subject matter is allowed. This includes any QST's of events or hamfests, especially if Drake radios are included

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our groups home page, as well as links to Drake information or your homepage.
Thanks to all members for your particapation.

From: Bry Carling
Topic: 4629 Message: 4629

For sale: Marker Crystals

100 kHz - $19.00 each
1.000 MHz - $16.00 each
10.000 MHz - $16.00 each

These are full size, hc6u, or wire lead crystals. In the case of
the 100kHz crystals, they are new manufacture, top quality
"tall hc6/u" crystals known as hc13/u. Some of the others are available
with wire leads. Shipping is additional.

4630. TR4C BAL MOD

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-15 20:33:06 UTC
From: Dick KF4NS
Topic: 4630 Message: 4630

Still puting the finishing touches on the ole rig and was using Garey's great CD for reference while determining the real condition of the filters. That completed (one is bad), then I proceeded to check the adjustment of the BAL MOD for proper CXR BAL as per the section 5 steps for alignment.

Right off the diving board I got twisted around. It says to adjust the bias according to the earlier steps in para 5-6 which says adjust for .1A, now key the rig in X-CW and if the plate current exceeds .15A adjust RF TUNE for .15 and if it is less than .15A adjust the CXR BAL pot for .15A , what is the deal with this ".15A" ?

Why do that after setting the bias for 1.0A at the beginning? I tried to adjust the pot and it does nothing. How critical should the reading be while adjusting the pot? How many turns are there to this pot?

My experience is with the T4-XB not the C but the
balanced modulator is about the same in both. I also don't
quite understand the above. The balanced modulator is
adjusted for null in SSB with no audio. There are two
adjustments, the pot and a capacitor. The null is very
definite. It should be set using a scope on the output of
the TX on a dummy load or a receiver sampling the output.

After tuning up in Tune or CW switch to SSB, the sideband does not matter. The exact frequency of the carrier oscillator must first be set with the modulator unbalanced so that the carrier is of equal strength on both sidebands. That assumes the filters have the same curve, meaning they are working right. Once you have this set adjust the balance pot for the best null you can get. If its not complete adjust the capacitor to improve it. You may have to juggle these two because they interact a bit. The pot has ten turns and will normally give you a null fairly close to the center of the range. If you can't get a null, or if one or both of the adjustments is close to the limit of its range something is wrong.
Quiescent or no-signal plate current can be set in "Tune" with the audio control at minimum but is probably closer if set in SSB with no audio but with the push-to-talk keyed. When the carrier null is correctly adjusted it will not change the no-signal current at all. The balanced modulator in the 4 series is very good and will actually meet its specs which are considerably better than most of the competition including modern stuff.

Dick,
First, you SHOULD be setting the bias in SSB, with mic gain ALL the way CCW, so there should be NO current except the idle current. When you go to X/CW, you are actually keying the rig and should have some output. It will often be more than .15 when you key it up in CW, but not with the "Gain" control fully CCW in my opinion. You may have to bring the gain up clockwise a bit to get .15A current. That make any sense?? Most of the Carrier Balance pots in Drake gear are 10 turn, so it may take a turn or two to notice a difference. I am NOT sure about the pot in the TR4C, as I have not been into mine yet. I will be there thought, as it now is NOT transmitting. :>(

One other thought. They want you to keep the rig under .15A (150 mils) to protect the finals from damage if you get too LONG in the tuning, hi.

4635. TR4C TX trouble

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-17 23:29:49 UTC
From: Dick KF4NS
Topic: 4635 Message: 4635

I am at my wits' end ! Just when I thought I had almost all of my ducks in a row this happens.

I decided to tune up on every band, upper and lower, so I could put the wraps on it. Well, it didn't go well.

Here are the results:

80M no output on LSB, S/B SW in ccw, USB ok,
40M no output USB, S/B SW cw, LSB ok.
20M full output on USB/LSB
15M no output on USB, S/B SW ccw, LSB ok.
10M no output USB, S/B SW ccw, LSB ok.

All tests run with dummy load and viewed on O'scope. CXR OSC reads 8.99993mhz on counter. CXR BAL tests good. Bias reads normal on all bands, both S/B's. RF TUNE peaks on all bands, USB and LSB using XTAL CAL. I thought, well, must be a bad filter but I can't rationalize it.

I am ready to just stick it in the closet and forget about it for the next 10 years (should I live so long)

Dick,

the filters are bidirectional. that is, receive and transmit signals are passed in opposite directions. so, if there were a filter problem you would likely experience it in receive also. with an oscilloscope available, you should be able to trace the 9.0Mhz oscillator to the filters and see if the switching is behaving correctly. which it sounds like it is since you can apparently transmit 20-meter USB and LSB.

your problem is indicative of a 9.0Mhz oscillator that is off frequency and therefore has skewed the mixer products out of the passband of one filter, and passing the wrong sideband. however, you claim the oscillator is exactly 9.0Mhz .. so I should give this more thought.

tracing the signal with an oscilloscope and a counter, should allow you to find where the USB and LSB signal components end.

NF7Z, daniel

NEVER MIND, I am the worlds biggest dumb alpha sierra sierra !

It seems like I will never get it through my head how this Drake radio is designed. I keep thinking I can tune in the SIDEBAND X position using X-CW and then switch to the ccw position of the SIDEBAND switch (I corrected the 40M SW position below) and still see power out in the X-CW position.

I keep thinking like HEATH and COLLINS, and others where you can usually switch to CW and hit the key whether you are in USB or LSB during a voice QSO. I just need somebody to hit me up side of the head, but that would just scramble my brain even more I guess.

Thanks for everybody's extreme patience with my ridiculous postings. You are such a great bunch of guys to tolerate my idiotic ramblings.

4638. MN4 Tuner, G5RV, ladderline, & headaches

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-19 16:03:45 UTC
From: billykatzz
Topic: 4638 Message: 4638

I finished putting up my homemade quasi-G5RV with homebrew ladderline (quasi, since the ladderline is longer than 31 ft, it's more accurately a ladderline-fed doublet) and dang if I can't get my Drake MN4 matching network to adjust it!

It was a big disappointment for me today when I finally rigged and hooked up the antenna and the sucker loaded up like a rusty bedspring. I initially tried it out with a Balun Designs 1:1 ferrite core balun, then my homebrew airwound 4:1 balun, to try mating it to the short run of 213 into the shack and MN-4 tuner (the MN4 doesn't accept balanced feedline). No dice. I don't know if the problem is the antenna, the ladderline, the coax line, or the MN4 matching network.

I put my 40 meter dipole back up for the time being, but it would be nice to have an antenna that would perform a little better for me on 80 an 20. I've worked quite a few hams who've used G5RV's and they seem to do a pretty good job for them.

I'm stumped. Could there be some problem with the MN4? Shouldn't the unit be able to achieve a decent match going into most impedances? I was thinking about opening it up and checking for any burnt components/contacts. Could excess dust inside affect the tuning? Any advice or assistance would be appreciated.

Bill
I use a 102 ft G5RV and it works very well indeed
I have Balun Designs LLC 1:1 choke balun between the 33 ft ladder line (450 ohm commercial stuff) and coax (RG-8)
I have found that the length of coax between the ladder line and rig is touchy to crical. The coax run from bottom of ladder line to rig, in my case, turned out to be near electrical 1/4 wave of coax on 75m and it was very tough to adjust and didn't perform very well. I added 12 ft of RG-8 to the feedline and now it is the best wire antenna my small lot ever had.
The MFJ antenna analyzer is a great asset for resolving problems like that.
When the G5RV is right---it works. Although sometimes you have to refer to it as dipole fed with open wire line. There seems to be some closed minded individuals out there on the bands that absolutely hate them.
Paul K0UYA
PS I tried the antenna fet right at the bottom of the ladder line through a classic open wire tuner (Johnson Matchbox)and it was not a positive experience.

4641. Re: [DrakeRadio] MN4 Tuner, G5RV, ladderline, & headaches

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-19 18:25:51 UTC
From: K4GM-George
Topic: 4638 Message: 4641

Bill,

I assume you are using a T4XB or C??? If you are, the pi-network on the transmitter can probably match the antenna on some bands w/o the need for a tuner. Now you might need to install a balun to "convert" the ladder line to coax to screw on to the xmtr. I am using a 135 foot dipole fed with ladder line which is brought into my shack via a 4:1 balun. My T4XC loads beautifully on 80m as does my L4B w/o a tuner. Now on some bands a tuner would definitely help. My point is that an antenna tuner does not tune the antenna; it simply transforms the impedance into one the transmitter will match. I find that many hams not used to using classic gear with pi networks are astounded to see an old xmtr load right up!.

Good luck, 73, George K4GM

Once you change the feedline from the 30 some feed value, you no longer have a G5RV antenna. YOu just have a random wire type. The 31 feet of feedline is to match the antenna to near 50 ohms. I would go with the 31 feet of open wire and put the choke 1:1 balun and then feed it with the coax.

The MN4 may not have enough range to match an antenna that is really way out of the impedance range.

4644. Is this normal on the SPR-4?

Topic: 4644 Message: 4644

I just acquired a very good condition SPR-4 receiver with all 23 xtals installed. Reception is pretty good on it, I love listening to hams. My only complain is the background noise. With no antenna connected and the RF gain at max. I get a lot of noise at half the volume, and the S-meter shows zero. If I lower the RF gain to 40 percent or less, the noise is gone, so I assume is not the AF section creating the noise, must be on the IF amp or something. Is this the way your SPR-4 behaves or is something wrong with this radio? Thanks for any help in advance.

4645. Hustler 5TBV Antenna - HELP!

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-11-21 21:21:32 UTC
From: Bry Carling
Topic: 4645 Message: 4645

Hi guys - I am finally finishing assembly of a Hustler 5TBV Antenna
that I inherited from Doc, KD4E about 3 years ago.

I have almost finished putting it together.

However, I found an EXTRA PIECE that is not discussed or described
in the manual as far as I can see!

It looks like a hose clamp with three fins attached, each about 6" long.

Does anyone know what the intended use of this gadget might be?

Here is the picture:

http://www.af4k.com/extrapiece.jpg

Any clues would be immensely appreciated before I put this puppy
up in the air.

That piece is the 80m radials. it mounts just under the 80m trap at the top of the antenna.

Tighten down the clamp and then bend the flat pieces to a 90° .

Hustler 5-BTV New Assembly and High Performance Installation Instructions (3.3M pdf)

Specifications

Band coverage: 10, 15, 20, 40 & 75 or 80 meters (Easily tunable to either)
Height: 25'
Weight: 17 lbs.
Materials: heavy wall, high strength aluminum tubing & heavy duty aluminum bracket. Stainless Steel clamp and hardware.
Mounting: Ground mount with or without radials, roof or tower mount with radials.
Power Capacity: Full legal limit on SSB /CW.
SWR: 1.6:1 at band edges
VSWR @ resonance: 1.15 to 1 or better
Bandwidth VSWR: 2 to 1 or better at band edges on 10-40 meters (100 KHz. On 75 or 80 meters.)
Wind load: 29 lbs @ 70 mph. 5-BTV 2:1 SWR Bandwidth 5-BTV Chart

Ground, Roof or Elevated Mounting? Radial wires or no radial wires? High Performance From Your Hustler BTV(509K pdf)

New-Tronics Antenna Corporation Limited Warranty
New-Tronics
Antenna Corporation warrants it's products to be free of defects in the material and workmanship and extends this warranty under intended use and normal service conditions to the original owner for a period of one year from the date of purchase. This warranty does not apply to any product that has been repaired or altered in any manner and it void for any damage due to accident, neglect, unreasonable use, improper installation of any other cause not arising out of defects in material of workmanship. The obligations of New-Tronics Antenna Corporation are limited to repairing or replacing, at it's option, any product or part that is returned to the factory all transportation charges prepaid, accompanied by proof of purchase and which examination reveals to have been defective within the warranty period stated above. New-Tronics Antenna Corporation does not assume nor is any person authorized to assume for it, any obligations other than that herein stated. Any implied warranties, including but not limited to fitness for a particular purpose, are limited in duration for the above one year period. New-Tronics Antenna Corporation shall not be liable under this warranty, or any implied warranty, for the loss of use of the product or for other consequential loss or damage incurred by the purchaser. Some

states do not allow the exclusion of limitation of implied warranties of consequential damages and so the above exclusions of limitations may not apply. This warranty gives you the special legal rights and you may have other rights that vary from state to state.

>
>
>

Once you change the feedline from the 30 some feed value, you no longer have a G5RV antenna. YOu just have a random wire type. The 31 feet of feedline is to match the antenna to near 50 ohms. I would go with the 31 feet of open wire and put the choke 1:1 balun and then feed it with the coax.

The MN4 may not have enough range to match an antenna that is really way out of the impedance range.

I've just picked up a really nice T4X and R4B set up, seems to work FB apart from if I want to use the Rx as a seperate unit the sensitivity goes way down, using the Tx as the main control in transcieve its fine.
Am I missing something here?, I have taken the precaution of ordering a NOS 6HS6...

Thanks Tim M0AFJ

Tim,
Sounds like that might be a dirty switch. With the front of the R4B facing you, on the left hand side, there is a switch for VFO or XTAL control. Work it while listening and see if that doesn't help. Those are notoriously intermittent, and some just solder on jumpers to eliminate the problem. Hope that helps!!! It has saved me MANY times, hi.

Hi Don, that did the trick, great tip. Rigs working well now apart from the dial calibration of the Rx, I've had to move the actual vernier dial to get it in but really I think the VFO needs resetting, I don't suppose you have any instructions for that?, all the manula says is `don't do it send it back to the factory'!!

Hello all
Heard a very strange transmission on 14.010.5 (CW) today. First heard it around 1425 UTC and it went on until about 1440 UTC. It was automated but shifted freq up and down a few khz after each call.
I quote " SOS SOS SOS Sahara/CN Assassin ". Tried responding but nothing.
At the time the band was open to the U.S. so did anyone on the other side of the pond hear it? The transmission was S9 here and I doubt that it was a mobile.
Don't know what to make of it!
Cheers
Vic

Tim,
That "tip" comes from the distant past, probably given to me originally by Bill Frost formerly of Drake service, hi. On your dial alignment, if it is beyond what you can do with the instructions on pg 16 and 17 of the R4B manual, I would suggest a search of the www.wb4hfn.com site where you will find a couple of nice articles on the PTO workings. Also, maybe Garey will chime in with some other words of wisdom!!
73,
Don, WB5HAK

I'm not sure I understand what it wrong with the
calibration. It will normally vary a little from band to
band because the crystals are not perfectly on frequency.
There will also be some variation from end to end. I am not
sure of what is typical but both of these are the reasons
for the movable pointer and dial skirt. A VFO that is very,
very far off could indicate that the stops are not set
correctly, i.e., from the gears being out of synch, or an
electronic problem but I think the latter is rare.
Note also that the dial is held in a clutch and can be
slipped. This can be done with the end of a finger and
requires only that the case be removed. The dial should be
```

set up so that its right in the center of a band with the
red pointer centered in its range.
There really is not much in the way of adjustment in the
VFO. Drake VFO's seem to be very reliable and stable.

The BTV series antennas are nut wired to the based of the antenna. This item allow you to connect a Pl-259 coax plug to the antenna rather than direct wiring the coax to the antenna. I hope this explanation helps. 73 John WA9WHD Lutz. FL

Thanks John - but no, that is actually a piece they tell you to put at the base of the 75m coil on the 5BTV. Nothing to do with radials.
I didn't understand the remark about it being "nut wired."

I had about 150 helpful answers , copies of manual pages etc. etc. etc. sent to me on this ove rthe past few weeks from a bunch of great hams all trying to help me.
Made my first few contacts with the rig on it yesterday and today.... KP4 on 40m and checked into SouthCARS on 7251 kHz, so all in all it works well.

They don't document that piece very well, but yes it is a kind of capacity hat or matching stub for the75m trap when you add it to the 4BTV part for 40-10m.

The BTV series antennas are nut wired to the based of the antenna. This item allow you to connect a Pl-259 coax plug to the antenna rather than direct wiring the coax to the antenna. I hope this explanation helps. 73 John WA9WHD Lutz. FL

Brian (and Gary) - sorry for the confusion. I based my reply on the photo from

http://www.dxengineering.com/Parts.aspID=3434&PLID=141&SecID=16&DeptID=8&PartNo=HUS-5BTV

which shows a picture of the coax adapter.If I had read Gary's questions more closely I would have realized that his question had nothing to do with allowing PL-259 acessiblity to the base of his 5BTV antenna, which at least in my case, has the coax cable directly wired ("nut wired" :)) to the base of my 4BTV.

Sorry for the confusion - 73 John WA9WHD

From: Steve Torma
Topic: 4660 Message: 4666

Hi Peter,

Name here is Steve Torma, located in NJ...zipcode 07924, and ran across this/your email looking for a 500 hz cw filter for your TR-4CW. I'm selling some of my Drake gear, incl. a TR-4CW/RIT, and have bought a bunch of spare parts for it which I will be selling also.

As a result, I've got 2 new-old-stock, unused/untested, Network Science Inc., #7709 9.0 - .500/6 cw filters (9.0 mhz IF, 500 hz bandwidth, 6-poles) for the TR-4CW,CW/RITs, and I'll sell one of them for $90 Shipped-CONUS-Only, and payment via US Postal Service Money Order Only. Pricey, I know...sorry, but it's less than I paid for it.

If any interest, feel free to email me. Tel# here is (980) 766-0671, but I do use dail-up service for web, and I let my neighbor use my computer when I'm at work, so getting me by landline may prove difficult.

Anyway, thanks for your time; and if you already found a filter, well..good-find!

Regards,

Steve

Grant -

Your problem is almost certainly C192 and/or possibly C190. You can verify by just bridging a good cap across one of those with clip leads as the problem is high ESR, not leakage.

If they are gone, the can cap C90 and tubular cap C91 are probably not long. A good fix is the re-cap kit from 'hayseedhamfest.com'. Tom has a complete set of all electrolytics for a very reasonable price. All electrolytics in that receiver are way past their life expectancy, and a 'shorting' failure can take out a power transformer. Be sure you have the correct size fuse in place!

4679. B Line Working and new TR-4

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-02 00:29:06 UTC
From: PaulG
Topic: 4679 Message: 4679

Turned on the B line for the 1st time this season and it seems to still be working so thanks for all the help in troubleshooting.

Last week I bought a TR-4 with AC3, MS4 and RV4 that was advertised as I thought it was working when I bought it but wasn't so am getting ready to try it out. It looks pretty good and hopefully will not be too far gone.

My shack is on the 3rd floor of my 1901 home and has no heat so when it gets cold all the tubes add some heat.

Now have the B line the TR4 set up AND the 2B.

Happy Holidays

Paul K3PG

4682. RIT control for R-4B

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-02 09:02:03 UTC
From: mike
Topic: 4682 Message: 4682

I've put the schematic for a "RIT" (Fine Tune) control in the Files section.

It has a range of +/- a couple of hundred hertz - perfect for easily getting natural-sounding audio on SSB.

It's just a varactor controlled by a Log. pot. connected to the FSK terminal of the PTO.

I fitted a small pot (with 1/8" shaft & 1/2" knob) in the bottom centre of the front panel (where the little circle mark is).

The mod was done on my R-4B, but I see no reason why it wouldn't be equally successful on any model with the same PTO.

Regards,
Mike

Brian -

The "correct" replacement relay is the P&B (Tyco) R10-E1-Y4-V2.5k, same relay used in the "late" T-4XC and TR-4C, which IS available from Mouser and Newark among others. About $15.

If your old relay is a Varley with a 15k coil, you need to add a 1.5k 1W resistor in series with the coil, otherwise a drop-in replacement. Look at the socket for V10, the 6FQ7 (or 6EV7). If there is a 1.5k, 1W resistor connected between Pin 6 and Pin 9, just plug in the new relay. If there is NO resistor, remove the wire connected to Pin 6 and move it to Pin 9, add a 1.5k, 1W resistor between Pin 6 and Pin 9, and plug in the new relay.

The 15k ohm coil relays were failure prone, primarily because of the very fine wire needed. The bobbin would swell, especially in humid conditions, stressing and breaking the wire. This is why T-4XC's that have been stored in the garage for a while often have a bad relay! The 2.5k ohm coil of course uses considerably larger wire.

Brushed metal inserts for the MAIN TUNING knob are available from Charlie Talbot, K3ICH. He sells on eB* as 'fixit-fox'.

4685. Initial TR-4 Test

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-02 20:18:48 UTC
From: PaulG
Topic: 4685 Message: 4685

Test Conditions
I used the following from my working B line
AC-4, Speaker, back up wire antenna.
Desk Mic

RX
Copying weak signals but S meter stays on about 3 and does not move with signals that are S9+

'Cal' function tones are heard

RF tune peaks the noise

TX
X-CW (tune) into dummy load puts out over 120 Watts. Transmit tuning seems 'normal'

'SSB' When PTT on mic is pushed puts out about 4 watts and there is no modulation or change regardless of 'Xmtr Gain' setting.

RX not going into full mute Meter goes to S9 but does not go to full scale. It will go to full scale with the RF gain control.

Overall condition is good and clean. I have no idea of history or when it may have been working last.

Any ideas of where to start?

My guess would be to start checking tubes.

Paul K3PG

4686. Re: [DrakeRadio] Initial TR-4 Test

From: William Houghton
Topic: 4685 Message: 4686

If you haven't already done it....

1 - DeOxitIt on the switches,
2 - Fader Lube on the pots
3 - LOOSEN and Retighten all of the screws that secure solder lugs to the chassis (this often includes tube sockets). My TR-4C had loud objectional hum until I tightened a screw close to the 6AQ5. Oxidized ground connections can cause all sorts of odd & difficult to troubleshoot problems.
4 - DeOxitIt on the tube pins and tube sockets.

Then test tubes. Leave tubes that test marginally weak in place for right now. Tube testers aren't precise and so the "weak" tube might be fine in your radio. I do place a small colored adhesive dot on the weak tubes so that when I'm troubleshooting a problem and a tube did test "weak" I'll know it (Avery Labels makes these dots).

Take your time, have fun, be patient, and be thankful Garey is in the group (he knows just about everything you need to know to get a Drake working again).

73, Bill

4688. Help with R7A

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-03 15:10:57 UTC
From: w1fued@sbcglobal.net
Topic: 4688 Message: 4688

My R7A has developed a problem with , I think, is associated with the product detector and am detector, not turning on. When I turn on the calibrator, it seems to act as a product detector. I have followed the wiring and it seems I am not getting the +10 volts that should be present on 2/3 if board that ultimately turns on the product detector/ am detector.
I have followed the +10 v line back to the ssb/am switch (which is good),no 10v. at the switch. Now I am lost as to where the 10v (should)come from. The passband tuning board? It seems the wire goes to the passband switch, but them I cannot find it.

Also, my RIT seems only to work in the SSB/cw mode when I turn on the calibrator.I think this another clue to the problem. I dont remember if this is normal or not. I am wondering whether this maze of wires at the switches has somehow lost the 10v, but dont know where it comes from on the parent board or passband board to check.

I guess the calibrator is reverse biasing the diodes in 2/3 if board
as it should. All diodes test good on 2/3 if board.

This is my first adventure into the r7, maybe I should stick with the tube stuff.
Any advise would be greatly appreciated.
Thanks,
Ed

Ed -

OK. +10V required to switch to the CW/SSB detector on Pin 10/35. Your observation that the Calibrator ALSO turns on the CW/SSB detector is correct, this occurs through Pin 10-4, via CR1007.

The +10V comes from the Passband Tuner board (#11) Pin 11/37 via switch S-4C, the AM-SSB/CW switch, and controlled by Q1107. I have to admit that I cannot see where the DC bias actually 'comes from', I would expect a pull up resistor somewhere, but not there. In SSB/CW there should be +10V on Pin 11/37,

I must be missing something somewhere. Actually I think there's a resistor missing! :-) Hopefully Bill or someone else knows??

Anyway, you need at least a couple-three volts minimum at pin 10/35, and supposedly you'll see 10V on this pin in SSB/CW.

Subject: Re: [DrakeRadio] Help with R7A

Ed -

OK. +10V required to switch to the CW/SSB detector on Pin 10/35. Your observation that the Calibrator ALSO turns on the CW/SSB detector is correct, this occurs through Pin 10-4, via CR1007.

The +10V comes from the Passband Tuner board (#11) Pin 11/37 via switch S-4C, the AM-SSB/CW switch, and controlled by Q1107. I have to admit that I cannot see where the DC bias actually 'comes from', I would expect a pull up resistor somewhere, but not there. In SSB/CW there should be +10V on Pin 11/37,

I must be missing something somewhere. Actually I think there's a resistor missing! :-) Hopefully Bill or someone else knows??

Anyway, you need at least a couple-three volts minimum at pin 10/35, and supposedly you'll see 10V on this pin in SSB/CW.

Subject: [DrakeRadio] SOS?

Hello all
Heard a very strange transmission on 14.010.5 (CW) today. First heard it around 1425 UTC and it went on until about 1440 UTC. It was automated but shifted freq up and down a few khz after each call.
I quote " SOS SOS SOS Sahara/CN Assassin ". Tried responding but nothing.
At the time the band was open to the U.S. so did anyone on the other side of the pond hear it? The transmission was S9 here and I doubt that it was a mobile.
Don't know what to make of it!
Cheers
Vic

4693. NEW! Service Supplement CD for R-4A / T-4X

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-05 23:26:01 UTC
From: Garey Barrell
Topic: 4693 Message: 4693

I have received numerous requests for a CD covering the R-4A and T-4X.

Here it is!

Hopefully people have not given up, or the requests were not all from the same person, but ...

This was not an easy one, since it seems there were quite a few changes in the R-4A AFTER the "last known" schematic, 1026665400, requiring a revised schematic. This CD is for the 11 tube version of the R-4A (s/n 4054 - 6999). The early version is 'coming', but I had to start somewhere! The T-4X was also in a state of flux, as I have found three distinct versions of the schematic, none dated or otherwise identified. Of course both (now three) R-4A schematics are included, plus all three (now four) T-4X schematics.

There are 58 pages, 32 of which are in high resolution color, in the Service Manual. Along with the Manual directory with quality scans of the C-4, L-4B, FS-4, MN-2000, W-4 and other original manuals, there are the usual batch of miscellaneous files with field changes, modifications, troubleshooting tips, etc.

Still the same low price, $25 delivered to the US, slightly higher elsewhere. All the previous CDs are still available too!

4694. TR-7 audio failure

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-06 18:07:17 UTC
From: Craig Roberts
Topic: 14 Message: 4694

The receiver audio output on my TR-7 is dead.

I normally keep the audio output (via its back panel jack) connected to my computer sound card as part of my digital modes interface. I've been doing this for years without incident.

However, yesterday the stereo phone plug into the sound card apparently became partially dislodged and effectively shorted the radio's audio output line. I was unaware of this initially since I had turned on the radio to allow it to warm up, left the shack, and didn't return for about 30 minutes. By then, the rig was mute.

Audio via the audio out jack, speaker line and headphone jack are all dead though S-meter fluctuations indicate that RF is still being detected normally.

What might I have blown? If it's the audio amp IC, with what can I replace this obsolete component? (I'm hoping for a 1N4148 diode or transistor burnout).

Many thanks,

Craig
W3CRR

Craig -

Most of these IC amps are short-circuit protected, so I would suspect
C1159 first, followed by C1174.

If the amp is really blown, earlier units used an LM380. I don't know
if they are pin compatible. It may be possible to put a TDA2002A in there.

It seems like I have heard of a sub for the SL61545, but I can't find it
at the moment. Perhaps someone else knows what it is.

Craig -

It's coming back now..... I don't believe I've ever seen a TR-7 with
an SL61545 IC in it!! All I've ever seen is the LM380, which is still
available from several sources, and IS output short circuit protected.
Apparently the '61545 was gone even before the TR-7 was built. Perhaps
lost in the time between original design and production?

Too many things, not enough neurons ...

From: Craig Roberts
Topic: 14 Message: 4699

Many thanks to Garey for his excellent advice on resurrecting my TR-7's dead audio.

As it happens, no component replacements were necessary. My radio was, in fact, apparently suffering from that mysterious and not uncommon TR-7 ailment: "Acute Connectoritis."

I had removed the supposedly faulty audio board for the purposes of visual and olfactory inspection. No unplesantness was noted. Nevertheless, I was about to log onto Mouser to order an electrolytic and tantalum to replace the components I assumed I had fried when I decided to plug the board back into my radio just to keep it safe until new parts arrived. "What the heck," I thought, "why not turn on the rig and see if" [defying logic and entering into the realm of myth] the wound had healed itself overnight.

By golly, it had.

Incidentally, this radio, a late model TR-7 with the "split back", actually did have an SL61545 audio amp IC in it. My early model "spare" TR-7 has the LM380. Curious, ain't it, since -- as Garey noted -- the LM380 is still available and the SL61545 is obsolete.

Of course, boards could have been swapped by previous owners or service techs. Both rigs, though nicely restored, show evidence of reworking.

Anyway, thanks again, Garey. Your advice ahs been stored away for future reference.

I don't know what kind of connectors the TR=7 and UV-3 use but card edge connectors and Molex connectors are notorious trouble makers. I used to work on MCI audio equipment, large recording consoles and multi-track recording machines, nearly all of the troubles could be cured by cleaning and working the connectors. But, this is also true of much other equipment even when the connectors are gold plated. While the gold may not corrode it can still get dirty. Many times just working the connector will fix it even without the use of contact cleaner.
BTW, this is also a problem with the audio and video connectors at the TV plant, they develop high resistance or intermittant problems. The only cure is frequent cleaning by working a plug in the jack. Can be a problem when you have thousands of them.

Denny -

Not 'deficient', just connectors. Rule of thumb, the fewer connectors,
the longer Mean Time Before Failure. Especially true in solid state
stuff because there just isn't enough current or voltage to burn through
even the slightest film of corrosion.

When your tube gear fails, simply unplugging and re-plugging a few
connectors probably isn't going to fix it! :-)

You're joking, right? This malady is not restricted to solid-state devices. Mechanical connections in high impedance/low current areas of tube circuits can be similarly affected. A good example would be the RX side of a T/R relay.

Been there, done that, easily done. I used some low capacitance Teflon coax that I had around, but I imagine ordinary RG-174/U or RG-58A/U would work for the RF part. Any old wire can be used for the control lines.

I think it's been said here and other places more than a few times, "
95% of TR-7 'failures' can be repaired by simply wiggling the boards in
their sockets." I often fail to mention that, thinking it's one of
those things 'everybody knows'! :-) I need to put a 'disclaimer' at
the front of each repair message..... :-)

Glad you got it fixed with no more pain than that!

Yeah, I know.... :-)

I seem to recall a rule of thumb from my NASA days that each connector in a system reduces the unit reliability by 1%. The connectors that we used were gold plated, hermetically sealed and $50+ each, and I think the rule applied if THEY were used. :-) The more critical a unit was, the fewer connectors it had.

Interestingly, with PC boards that had gold plated traces, we had to REMOVE the gold from the solder pad area before soldering. Seems the gold leached out into the solder, weakening the solder/copper bond. BUT the solder had to extend from the pad out onto the gold. Hmmmmmmm. The world of 'reliability' is a strange world indeed. :-)

Actually, I'm a bit embarrassed by my original inquiry about a lack of receiver audio output..

I had ASSUMED that because I found the audio output line cable dislodged and the failure was sudden that components had been fried.

I had ASSUMED that because all of the radio's circuit board connectors had been cleaned within the past few months that a bad internal connection was highly improbable.

Well, you know what they say about those who ASSUME.

I should have known better. With one exception, every problem I have had with the three TR-7s that I have owned have been due to "Acute Connectoritus." Next time, I'll check the connectors first. No, really. I will. (BTW, that's about the eighth time I've said that).

Worked some more on the TR-4 Today and now have transmit modulation after checking all the tubes and wiggling and poking.

Transmit seems to have good power and NOW has modulation as well.

Still have the following 'issues'

One sideband is not working and it does not seem to be the switch. The filter seems to be 'open' from listening to the RX and their is no TX through it either. Other sideband seems fine.

RX is still very weak strong signals are only moving the meter to S-3 or so. Cal tone is 10db over S9 on 40M. I am going to look at the antenna relay.

S meter goes to 50 over when the RF gain is turned down all the way, it does not Pin.

S meter only goes to S9-10 over when in TX

Any ideas on what other checking I can do.

Have sprayed and cleaned, set the bias on the finals, tested all the tubes,

Paul K3PG

Yeah, and I'm starting to sound like a broken record because anytime someone comes by with a strange 7-line problem, I tell them to check the connectors. That's why I was waiting for Garey to cover this one... :)

Interestig stuff, Garey. I knew that the gold leaches into the solder, but not that it was such an issue. I do know that NASA likes crimp-on connectors for reliability, and have read of the "tin whiskers" promblems with no-lead solder (abominable stuff, that).

From: Dick KF4NS
Topic: 4718 Message: 4718

A while back I recall a discussion about the heat in the AC4/AC4R. Now that my rig is back in the shelf along with the PS in the MS-4, I notice that the back of the AC4R is too hot to touch for more than a couple seconds. I worry about cooking the xfmr too much.

I could put a fan on the rear apron, and if so, is there a preference on the location? Also, would it make any difference which direction the air flow goes?

After rebuilding my AC-4 I decided to *NOT* mount it in the MS-4. The cable from the AC-4 to the T-4X is so long (5 feet, maybe?) that it's easy to find a place to put the power supply where it's out of the way but not boxed in.

Considering that there is no direct intake, I would blow air onto the supply. I personally have never felt that much heat coming from the supply. I do not have either of my AC4's mounted in the MS4 housings. Maybe that is why I don't have the problem. I do not use fans either.

Generally, transformers can and do run hot enough that you can't leave your hand on them for very long. They will be fine like this..but...heat does deteriorate plastics and varnishes like that used inside. Electrolytic caps also have reduced lifetimes depending on heat. So I have elected to add a silenx super quiet fan to my AC4. I drilled a series of holes in a pattern to match the 80mm fan. The fan is mounted on one end of the long side of the aluminum cover. It has holes along the sides to allow air IN so the fan draws air OUT. If you want to see pictures of this, I can take a few.

I agonized over doing this to the cover but have no regrets at this point...The PS runs cool enough that it is hard to tell it is on. It still fits inside the MS4 if required, and is dead quiet. These silenx fans are about 7.00 bucks.

I added similar fan to the PS for my TR7 as well. Many commercial power supplies use fans for continuous operation even though the transformers are rated to run at elevated temperatures.

FOR SALE:

1) BOX of 10 Ceramic Variable Capacitors. Various values from 30 pF
and up. Some transmitting, some receiving. All ten for $20.00 plus shipping.

2) 100 kHz crystals - new, tall type hc13u calibrator crystal as used in all
tube era radios. FIts the same soicket as an hc6u crystal. Available for
$19.00 each plus shipping.

3) Lacing cord for wiring harnesses. New, 300 yard spool available for
$12.50 plus shipping.

4) Pair of 2E26 transmitting tubes. Used, good tested tube pair for $5.00
plus shipping.

5) EIMAC 4-65A transmitting tube with ceramic socket in excellent condition.
QTY 1 available for $8.00 plus shipping.

6) RCA 832 mil-spec transmitting tube - looks new.
QTY 1 available for $5.00 plus shipping.

7) G.E. 6997 VHF transmitting tube, used. Looks OK.
QTY 1 available for $2.00 plus shipping.

8) Drake Crystal for R4A, R4B or R4C, covers 10.0 - 10.5 MHz
QTY 1 available for $12.00

9) Group of hc6u crystals on 7000 kHz, 7100 kHz, 7159 kHz, 7170 kHz,
and QTY 2 X 7174 kHz. TOTAL of six mil surplus crystals for $12.00
plus shipping.

10) Pair of FT243 crystals on 3880 kHz. One for you and one for a friend!
These are available for $10.00 each plus shipping.

11) Broadcast band FT243 crystals. 1200 kHz, 1300 kHz, 1475 kHz, 1600
kHz, 1585 kHz. Available for $14.00 each plus shipping.

73 and thanks for looking.

Glad I was able to help Dick. These AC4's lasted 45 years without a fan even when installed in the MS4, so I believe that out of the restricted area it would last maybe 70? Hi Hi. I rebuilt one of mine with the Heath Kit site AC4r board (it wasn't bad but what the heck) and it doesn't run any cooler. Back in the day heat was the norm and I never heard of all this fan stuph. I guess it doesn't hurt to give it a blower but just seems a waste of time. With all this alarmist global warming trash (single digits last 2 nights here in TN) people are worried about extra heat (bring it on!!!!!!). I like warm otherwise I would move north. I digress.

I see both the yahoogroups and zerobeat lists are listed on this thread, but I'll reply with both anyway. (I personally don't feel cross-posting to both lists is a wise idea, better then to stick with just one list, why have two ?)

Another reason to not have the AC-3/4 in the MS-4 - my shack is out in the garage, and every spring the little birdies insist on trying to build nests in the garage despite the fact the door is closed during the night.

Well, I luckily noticed the little birdies had thoroughly stuffed a nest in the back of my MS-4, and had I not noticed it, a fire would have been probable had I turned it on.

4728. TR4310 & TR7 comparison??

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-16 16:12:55 UTC
From: Craig Roberts
Topic: 4728 Message: 4728

I have long wanted to rack mount one of my TR 7s in order to consolidate space in my shack/audio production studio.

Accordingly, I seized upon the opportunity to purchase a TR 4310 front panel from an eBay vendor a couple of days ago and anxiously await its arrival. It APPEARS as it the front panel swap should be trouble-free asince the control layouts seem identical. It looks as if only the internal speaker will need to be relocated (I prefer a front-firing one anyway). Am I correct?

I know that the circuitry differs in the two radios with the 4310 using the RV-75-type tuning scheme. Are there any other significant differences or useful ones i can incorporate into my TR 7 / "mock"TR 4310?

Thanks, gurus,

73,

Craig
W3CRR

There are shelf units available for racks, perhaps one
of those would accomplish the purpose without having to
modify the rig.

4730. Drake R4C PTO drift - solved

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-16 23:01:40 UTC
From: arsnf7z
Topic: 4730 Message: 4730

greetings ..

I've told this story here before and now that the issue has been vanquished, I thought it might be of some interest to others to detail a problem that has lingered on since I bought the R4C new in 1976.

at that time, I only owned the R4C that I bought as a present to myself when I graduated from Stanford. I had a R4B previously, and was never satisfied with the audio. there was always a rasp on SSB that I never heard on the various Japanese radios on display at HRO. I traded the R4B and a Hallicrafters HT-32B for a new Drake R4C with all the goodies and filters. it always seemed to drift outside of specifications, but was certainly useable with continuous corrections applied. I didn't have a transmitter so it was just a nuisance and quickly forgotton.

fast forward thirty-five years and with a resurgance of interest in vacuum-tubed equipment, I resurrected the R4C and bought the matching T4XC and a TR4C transceiver. I brough everything up to spec, electrically and aesthetically and essentially have like-new Drake equipment in the shack. the one issue was the drift on the R4C. the PTO(s) in both the T4XC and TR4C were rock solid, but the R4C drifted about 1.5khz over several hours. the spec is essentially 100hz after warmup and the R4C exceed that by an order of magnitude. something was clearly amiss.

I initially thought it was a simple matter of heat. a poor design, the class A audio stage radiates heat up to the PTO along with a dropping resistor for the PTO supply, and all this was exacerbated by the noise-blanker option I had installed that acted as a ceiling to contain the heat. I can't tell you how many iterations of swapping out a PTO from a spare RV4C, using a separate and regulated 11 volt supply for the PTO, and several additional measures in my attempts to find the problem. nothing worked, except I noted that when exchanging the PTO for the RV4C PTO, the drift was considerably less, punching a hole in my heat-buildup theory. of course, that really didn't make much sense because Drake would have seen this same condition in the design. the heat on my R4C was certainly not unique!

out of frustration I tore into the PTO this week looking for clues. the 1N714 zener was slightly out of spec and replacing it yielding nothing new. when I disconnected the supply to the 2N3563 and measured the output at the FSK output-pin it was stable. replacing the 2N3563 buffer NPN transistor solved the problem. it was apparently a leakage problem that would load the 2N5950 oscillator stage excessively.

finally ... 35 years later, I have a R4C working to specification. I am still not pleased with the audio from the product detector. the TR4C audio sounds much better and neither sounds as nice a my Icom IC-7000 unfortunately. however, the Drakes are so much more fun to use and I rarely use anything else. the 75 and 40 meter bands are wide-open in the evenings here in the San Juan Island archipelago, and it would be fun to chat with other Drake fanatics on schedule.

I'll get around to redesigning the product-detector sometime in the next 35 years or so. the Drakes will still be here with me.

Thanks for sharing that fix, Daniel. That's what makes this reflector so valuable!!! I am going to rebuild one of my T4XC/R4C pairs over the winter, and will check these problems out as I re-cap and refurb. One pair will be for sale in the spring, if anyone is interested, but that's for another day, hi.

4734. MN4 Tuner, again (sorry)

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-18 03:03:51 UTC
From: billykatzz
Topic: 4734 Message: 4734

OK, I got my G5RV up to about 40 feet flat, cut the ladderline down to 34 feet, and my MN4 refuses to get a decent match. Tried the ladderline at 31 feet: no dice.

With the MN4, there's an 80A and 80B. I can get it down below 2 on the "B" side, fugedaboudit on the A side. Still, the impedance match is probably appalling if I checked the SWR.

I'm starting to wonder if it might be something in the MN4. No problem getting it to match on 40, 20, and 15. Is it possible the fixed caps for the 80 meter positions have gone south on the unit or something like that?

I hate antenna tuning problems. Reminds me why I gave up ham radio 40 years ago.

Bill
What is the length of coax between the ladder line and tuner? It does make a difference.
Assuming you are using coax with a 1:1 current choke between the ladder and the coax? If you are trying to hook the ladder to the tuner even if it is a balanced line tuner it doesn't work so pretty good.

4737. No receive audio on TR-4cW

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-18 23:29:15 UTC
From: Noodle10536
Topic: 4737 Message: 4737

I have no receive audio on my TR-4Cw after repairing a short in the T2 coil where the capacitor legs pass the chassis. I found a good used T2 coil, replaced it, re-connected everything put it all back together. When the T2 coil shorted it cooked the R2 resistor which I also replaced. There was one other capacitor, C136, in the board 5 that had only one leg attached. I fixed it and replaced the mic socket back to the original .204 socket. Now....no receive audio. I get very little noise out of the speaker and the noises seem to change a bit after different power on - off cycles. About the only thing that will create any noise is by turning the RF tune control. I tried tx quickly and that seemed positive. Anyone have any suggestions? Thanks, Peter.

4738. 12ax7

Probably been discussed before but is there a valid and cheaper sub for the 12AX7? The prices here are getting beyond a joke - $45 upwards for a single tube.
Also re the G5RV, my MN4 tunes up fb but I only use 29' 6" ladder line fed with 50 ohm co-ax via a balun to the ladder line. I have tried this on both full and half (14' 9" ladder line) 5RV's and all OK except 15m which is a bit sharp

Victor, You might try thetubedepot
http://www.tubedepot.com/12ax7.html
They have the sovtek for $8.95, which seems to be the lowest price I can find. The page shows others. Amazing what the guitar amps have done to tube prices...almost makes me wonder if some of the old manufacturers need to get back in the vacuum tube business!

My understanding is that the 12AT7 is pin compatible but has a lower gm spec (i.e- lower gain). If the tube mfgrs made tubes they way semiconductor companies test ICs, chances are the 12AX7 and 12AT7 are the same tube and are 'sorted" at final test on the production line and then marked.

I'm sure I have used 12AT7's in my Drake gear.

The whole " tone" issues came to mind months ago as I, too, was looking at 12ax7s. I went for a reasonable price, but I could not help thinking, " could it all sound better on the air with one of those Amp tubes?" I forget which site it was, but the tubes were described like so many types and grades of strings for a cello.

Has anyone tested them for difference? Given $1,000 for Christmas I'd buy the whole line and give it a try - then again how do I do those " A" " B" tests on the air and keep pulling tubes and inserting them while hot?

I mis-spent a lot of my life in professional audio.
Perhaps I am a heretic but I think in the main the idea that
tubes sound different than solid state stuff is due to the
generally poorer performance of most tube amplifiers. Tubes
themselves are not the difference but the need for
relatively high impedance matching transformers and the wide
use of single-ended power amps without any feedback results
in quite high distortion especially even harmonic
distortion. Perhaps, that, and the gradual overload
characteristic of non-feedback amplifiers is what the
musical instrument people want. Most tube radio receivers
use single ended pentode power amps to drive the
loudspeaker. These typically have on the order of five to
ten percent total harmonic distortion at rated power output
and gobs of intermodulation distortion too. Usually noisy
signals are easier to decipher when amplified by a low
distortion amplfier because the noise also produces

harmonics and, especially, intermodulation products. While a narrow band filter on the output can limit the harmonics it does nothing for IM.
The 12AX7, 12AU7, 12AT7, 12AY7, are all similar in that they are dual triodes with the same external envelope and base connections but the similarity stops there. the AX7 has an amplificatioin factor (mu) of 100, the AU7 of 20. They are intended for different purposes. The 12AY7 is similar to the 12AX7 but with a slightly lower mu and is a low noise and hum tube designed especially for low level audio use. The 12AT7 is a medium mu tube mostly used for RF purposes although its sometimes used for audio circuits. The general characteristics of the AX7 are similar to the octal base 6SL7 and the AU7 to the 6SN7 although the interelectrode capacitances are higher because of the larger elements and base. While circuits for one tube will often work with another plugged in they will not work correctly.
There are military and industrial type numbers for all (though I am not sure of the 12AY7). These are either identical to the commercial version or close enough not to make any practical difference. There are also European/British equivalent types that are again either identical or very close. Some have modified internal structure, mostly to reduce heater induced hum or microphonics.
IMO the only tube amp I ever heard that held up to modern solid state amps was the MacIntosh. I will add that some _early_ SS stuff was just awful and probably is the reason SS amps have a bad reputation to this day. Also, I suppose some people _like_ distortion.

Considering what some hams do with the digital equalizer
settings on their transmitters I would not be surprized.
Despite the very narrow band transmitted by modern equipment
its still possible to screw up the audio royally.

well, at least under some circumstances, some distortion *IS*
desirable-some electric Guitar players like it-and they like the way
tubes do it better than SS.
The basic issue seems to be that tube amps when pushed, mostly give
even-order distortion, while SS amps tend more towards odd-order
distortion(or maybe it's the other 'way around(I'm kinda "under the
weather" today.
The above is one the reasons NEW 6L6 tubes are STILL being manufactured today!

BTW, NO way on earth will you EVER see any noticeable difference on a
piece of ham gear.

Single ended tube amps have both even and odd order
harmonic distortion. Push-pull amps, if ballanced properly,
have only odd order distortion. The ear hears even order
harmonics as being consonant and odd order ones as being
dissonant. Generally odd order distortion products are lower
in level than even order ones. The class of operation of the
amplifier also affects the distortion products and there is
a difference between triode and pentode amps. Also, the
almost inevitable transformer in a vacuum tube amp
contributes to the distortion and can add some inharmonic
distortion if not well designed. Transformers that have
unbalanced DC in the windings, as is the case with most
simple single-ended amps, have some core saturation which
also contributes to distortion. To sound really good a tube
amp needs very careful design and the transformers are not
easy to make. Both Frank McIntosh and Herbert Keros (sp?)
had patents on transformer winding methods which attempted
to improve the conditions. This is not just the so-called
ultra linear circuit of Keros but a method of bifiliar
winding. McIntosh also had a unique winding method to
```

improve coupling without also increasing parasitic capacitances so that he could use Class-B without generating switching transients. Even McIntosh went to Class AB in later amps. Solid state amps do not, in general, need transformers for impedance matching so are free of whatever distortion they introduce. They have a set of vices all their own which can be just as bad as anything a tube amp does.
For musical instrument use the amplifier adds to the sound of the generator, whatever it is, in the instrument. Some types of harmonic distortion may be desirable, and, in fact, intermodulation distortion too. When it comes to this application all the rules of the purist are out of court.

1oldlens1@... writes:

>> Push-pull amps, if ballanced properly, have only odd order distortion.

Not totally true. While a properly-balanced push-pull stage will
effectively cancel the even-order products generated IN THAT STAGE, they will
NOT cancel even-order products generated in PRECEDING stages but will pass
them straight through, so the output will be PREDOMINENTLY odd-order
products with some even-order products that were generated in previous stages.

For thorough discussions & explanations of just about everything
related to audio amplifier design go to the following web site and see the "Tech
Info" section. There is even discussion about swapping 12AU7/12AX7/12AT7
tubes and what the effect will be if the tube is changed but not re-biased
and/or Ep remains the same.

http://www.aikenamps.com/ (http://www.aikenamps.com/)

Since I operate 99% CW "tone quality" is a pretty much a non-issue for
me.....I'd copy 750 Hz rotary spark and probably not complain (much) if
that was what was being used, although I probably *WOULD* complain about
fixed spark with, say, a 120 Hz interrupter.....it sounds like sh** and would
be hard to copy through much QRN.....

Hi Vic!

I suspect the tonal attributes part of the tube discussion will fade away fairly quickly.

If you need more clarification on your tube need(s), feel free to ask again.

Yes, this IS the Drake group, but sometimes we wander a bit and go a bit off topic, but several people DID find the excursion interesting, so....

Bear with us....we will be back 100% Drake again very soon!

Hint, HINT, gang!

I want to take this opportunity to wish everyone a very Merry Christmas and Chanukah. May you find peace and love, no matter where you live, and find food on the table, and good health in your home.

FWIW here is a list of tubes that is similar or
identical to the 12AX7
12AX7A (controlled heater warmup)
7025 (low noise)
7058 (14V heater)
6057
ECC 83
7729
6681
6881
12DT7
12DM7
12DF7
5751 (five star ruggedized type with u of 70 instead of 100)

Some may be available cheaper than the 12AX7. The really
high priced ones seem to those with the Telefunken brand.

4755. TR4C carrier problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-22 15:42:44 UTC
From: Dick KF4NS
Topic: 4755 Message: 4755

Hi Guys,
I just had my first lengthy QSO on 20M SSB since the restoration. A problem has popped up that was not an apparent trouble while doing all the testing on the bench.

After about a full minute of transmission the wattmeter starts showing a gradual climbing of carrier on the SSB signal. I have very good air flow, carrier balance was set during rehab, the finals were neutralized. Power output is over 200W with plate current reading around 500ma.

This does sound like a heat problem but as I said, there is plenty of air flow in and out of the rig. I have not tried lowering the output yet to see what that does but just wanted to put this to the groups ASAP before I do any damage. I know that one of the filters is bad but the 9mhz OSC. was tweaked with C130 to a satisfactory balance which left the CXR OSC still very close to 9MHZ. Let me know your thoughts.

I am using that combination. Something is needed between the two. The internal realy of the Icom will not stand up to the high voltage/current the Drake uses to activate the relay. I just used an external 12 volt relay between the Icom and the Drake. It is one that uses a low voltage coil and contacts that can handle the voltage of the Drake.

YOu can also use the 'soft key' from Harbach. If you have not replaced the high voltage capacitors, I would recommend looking into that. Harbach also makes a replacement board and capacitors for that.
I did install that capacitor modification in one I bought about 2 years ago. The capacitors with the leads comming out the ends seem to be difficult to come by at that voltage rating. If you do get anything from Harbach, I think I would spend a couple of more dollars and get several of the 'special' resistors for the high voltage supply that are designed to act as a fuse incase of a tube short.

Ken,

I'm late to the post here but...

As redundantly stated, you will definitely need a buffer circuit for keying up an L4B and if you already have an ARB-704 you should wire it appropriately to 746Pro DIN connector to save a tiny bit of timing delay and it can be powered by the 746Pro 13v DIN pin line too. Alternatively, you do not need to buy an amp buffer for the L4B if you have access to a couple of parts and the desire to make your own. There are many simple ways to do it and here is one idea. The L4B has about 28 volts on the relay which is grounded at about 30ma when keying up the amp. If you take an RCA jack and mount a TO220 Case style PNP transistor of appropriate rating and a gain of 40 or more with the collector tab soldiered directly to the outer shell of the RCA jack, the emitter soldiered to a wire fed over to the L4B amp key pin, and the transistor base in series with a 1K resistor to the center pin of the RCA jack you have your buffer with a total of 3 parts and a piece of wire to the amp. This will limit the current on the 746 Pro relay to less than 1ma on the contacts providing plenty of isolation.

However, this is not the primary issue you should be asking about when mating an L4B to an Icom746Pro; 756Prox... The L4B has slow and inconsistent relay operation when activated for transmit and you will certainly hot switch the amp with a 746Pro so break-in keying and VOX operation is likely to ultimately cause a problem with the rig and/or the amp. This problem can be verified by watching the SWR meter spike on the 746Pro when transmitting a CW note with the amp activated, in semi or full break-in or applying sound to the mic to activate in SSB VOX mode. The 746Pro keying RF output delay is about 10-12ms and the Pro's tiny relay within it adds about 220 microseconds (negligible) over the solid state transmit keying from the DIN connector. I never measured the L4B relay timing but I have 3 of them and they are consistently slower than the Icom's RF activation time. My guess is that they need about 15-20ms to stabilize the transmit transfer before applying RF. So my suggestion is to only use the L4B with manual Push to Talk for SSB and keep quiet until after you push the Mic button...

I have had mixed results with a "relay supercharging circuit" remedy for semi break-in that shortens the L4B transmit relay transfer time, such as the circuit from K6XX at

http://members.cruzio.com/~k6xx/radio/fastrelay.html

but it also slows the return to receive time as well. This can be applied to the RCA output amp side of the ARB-704. If you try this circuit the capacitor should be changed to about 5uf and the best capacitor value will depend on the gain of the transistor that you use. I used an MPSA42 transistor for this type of "supercharging relay circuit" with a different buffer circuit and it worked reasonably well.

You can also block the ALC line for added 746Pro xmit RF delay but that is another issue with mixed and limited results useful for Push to Talk and VOX SSB but generally not useful for fast CW operation. The problem here is that Icom doesn't provide inhibit transmit line or a choice of RF output delay upon transmit...

Hope this helps... What Say? 73

Alternatively, you do not need to buy an amp buffer for the L4B if you have access to a couple of parts and the desire to make your own. There are many simple ways to do it and here is one idea. The L4B has about 28 volts on the relay which is grounded at about 30ma when keying up the amp. If you take an RCA jack and mount a TO220 Case style PNP transistor of appropriate rating and a gain of 40 or more with the collector tab soldiered directly to the outer shell of the RCA jack, the emitter soldiered to a wire fed over to the L4B amp key pin, and the transistor base in series with a 1K resistor to the center pin of the RCA jack you have your buffer with a total of 3 parts and a piece of wire to the amp. This will limit the current on the 746 Pro relay to less than 1ma on the contacts providing plenty of isolation.
>
> However, this is not the primary issue you should be asking about when mating an L4B to an Icom746Pro; 756Prox... The L4B has slow and inconsistent relay operation when activated for transmit and you will certainly hot switch the amp with a 746Pro so break-in keying and VOX operation is likely to ultimately cause a problem with the rig and/or the amp. This problem can be verified by watching the SWR meter spike on the 746Pro when transmitting a CW note with the amp activated, in semi or full break-in or applying sound to the mic to activate in SSB VOX mode. The 746Pro keying RF output delay is about 10-12ms and the Pro's tiny relay within it adds about 220 microseconds (negligible) over the solid state transmit keying from the DIN connector. I never measured the L4B relay timing but I have 3 of them and they are consistently slower than the Icom's RF activation time. My guess is that they need about 15-20ms to stabilize the transmit transfer before applying RF. So my suggestion is to only use the L4B with manual Push to Talk for SSB and keep quiet until after you push the Mic button...
>
> I have had mixed results with a "relay supercharging circuit" remedy for semi break-in that shortens the L4B transmit relay transfer time, such as the circuit from K6XX at
>

> http://members.cruzio.com/~k6xx/radio/fastrelay.html
>
> but it also slows the return to receive time as well. This can be applied to the RCA output amp side of the ARB-704. If you try this circuit the capacitor should be changed to about 5uf and the best capacitor value will depend on the gain of the transistor that you use. I used an MPSA42 transistor for this type of "supercharging relay circuit" with a different buffer circuit and it worked reasonably well.
>
> You can also block the ALC line for added 746Pro xmit RF delay but that is another issue with mixed and limited results useful for Push to Talk and VOX SSB but generally not useful for fast CW operation. The problem here is that Icom doesn't provide inhibit transmit line or a choice of RF output delay upon transmit...

4765. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-26 20:07:18 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 4765

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

4766. Drake SP75 Speech Processor

Yahoo group: DrakeRadio (2006 — 2011)

From: kf0hr
Topic: 4766 Message: 4766

Hi List and Merry Christmas

Hooked up my SP75 Speech Processor to my TR-7 a few weeks ago. It won't pass audio when I push on the power button? It passes the audio when the power is off. I haven't really looked at the schematic much yet.
Where does a person start on this SP75? Who repairs them?

Thanks, de KF0HR Teran in North Dakota

4767. SP75 Speech Processor

From: kf0hr
Topic: 4767 Message: 4767

OK I opened up the SP75 and checked a few things. Looks like U4 13 volts shows 7 volts out TP-7. BFO 459 KHz is low at 300 KHz. Looks to have lots of problems or with low U4 output. Looks like TP-7 should be 9 volts. Will have to see if something is pulling U4 down or is the U4 running low? Also see the front audio green light stays on all the time?

Would like some help on what to check with this little SP75.

Thanks, de KF0HR Teran in North Dakota

Hi Teran,

I would say that U4 is a good place to start. Two volts low could be enough to upset the operation of the entire circuit. U4 is a 7805 that is being tricked into acting like an LM317 by adding resistors. Not the cleanest solution, but it works. You should be able to measure 5 volts between the middle leg and the output leg. If not, it is either bad or something is forcing it into shutdown. C29 may be suspect. If you replace C29, also replace C28 while you are at it. Not as likely, R35 or R35 may have drifted in value. If U4 looks OK, you can start lifting one leg of each of the decoupling resistors off the +9 power rail that feed individual parts of the circuit to see if you can find what is dragging it down.

As a side note, IMO U4 is not adequately bypassed for high frequencies. The manufacturers recommend certian values of capacitors right at the legs of the device - and they do so for a reason. I don't think this is your problem, I just mention it in passing.

4769. TR4310/TR77 question

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-27 19:07:44 UTC
From: Craig Roberts
Topic: 4757 Message: 4769

I am about to swap my TR7's front panel for one from a TR 4310. If anyone has a 4310 (or a TR77), please tell me how the panel is attached to the chassis. I will fabricate a couple of brackets, but would like to know how the factory did it.

Many thanks,

Craig

From: w3djk
Topic: 4770 Message: 4770

Hello my name is Dan and my call is w3djk. Well for christmas my parents bought me a TR-4C. The question I have is what would cause the x-cw position on the mode switch to not function properly? I works intermittinly I guess you can say. Now I noticed if I go between x-cw and x-am it will start work to perform tuning. Other times it sounds as if the relays are bouncing of chattering. Could it be a dirty switch or maybe vox or antivox settings. Any feedback will be greatly enjoyed. Thanks and 73, Dan W3DJK

4771. A short introduction and a few questions about TR-3.

Topic: 4771 Message: 4771

Hello

Let me start by saying Thank You for accepting me as a member to this group. I'm a Swedish ham with callsign SM7ZDE, name is Peter. My first contact with Drakes was in the Swedish army around 1979, I was an cw-operator and we were allowed to use our regiments club station in the evenings and at nights. Many years later, in 2008 I finally got my license. Today I have a 4-line, R-4C, T-4XC, MS-4 and AC-4, a Kenwood TS-440 and Icom 703.

I recently bought an TR-3 in cosmetically good condition along with a set of spare tubes on the Swedish version of Ebay. The price seemed right, around 100$. I removed top and bottom covers to check it out, it looks great on the inside, clean and all original, so far so good.

I cleaned all the wafers and tube sockets and the day after I fired it up after drying out. There is quite loud hum, both USB/LSB pilot lamps are on and a weak static noise in the background but no signals, not even from the calibrator. All tubes are glowing but I don't know how good they are. I gave the the USB/LSB switch/wafer an extra cleaning but still the same.
I use the power supply from my 4-Line. This is really not a surprise to me, it's an old radio.

I would like your opinions where and what to start with to bring my TR-3 back to life, I think the capacitors (electrolyt) maybe comes first, they are original as far as I can see and many of them are of the white paper type.

I wish everybody in this group a Happy New Year in 2011.

Hi Peter,

Loosen and retighten all of the screws that attach ground lugs to the chassis. Often these corrode over time. This often includes the screws on the tube sockets. Many of the tube sockets have ground lugs. I had a loud hum with my TR-4C and loosening and retightening the screws for the tube socket on the 6AQ5 fixed that problem. The reason to loosen (in my opinion) is so that you can turn the screw a bit and cause the screw head to scrap a bit of the gunk off.

You probably need to get the reciver working first because part of the process for tuning the transmitter is adjusting the RF TUNE control for maximum noise/signal.

73,

Bill

4774. Tuning the TR-4C

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-29 15:50:50 UTC
From: OH1KIO
Topic: 4774 Message: 4774

Hello Group!

I am happy to have a "new" TR-4Cw, and even though I am familiar with tuning tube finals of several Yaesus, I seem to be lost on how to tune this specific Drake to 3.5MHz.

Beginning with the dummy load, I have a very poor plate current dip (=can't find any). Fortunately I can find a tip by looking at the output, a small and really sharp peak to start from. Continuing to tune up from there, I can build up 60 watts of output with 350mA input (plate at 9, load at 4.5). I checked the dummy load (Palstar) with my antenna analyzer (also Palstar), which says it's 60 ohms +-0j at 3.5MHz. Tried several times to tune the Drake with different styles, but they all ended up with same settings and that is all output I get. Bias steady at 100mA, no problem.

Then to the antenna through a tuner (MN-75). VSWR with the dummy load is very close to 1, so I assume everything should be OK. But... When I switch the TR-4 from dummy load to the antenna, which I just tuned with the MN75 and checked with the same antenna analyzer (says 55 ohms +3j) from the same connection and cables as the dummy load, the VSWR jumps to 4. My logic says that even though I just tried to tune the rig to abt.50 ohms, the true result is something different.

I repeated the above process and ended up with exactly the same result. I double checked the setup by connecting another rig (solid state, can't mess the tune-up) same way to the MN75, and it says VSWR 1 to both dummy load and antenna, everything fine.

== So I am missing something in the tune-up of the TR-4, or should I start looking into the alignment of the rig? Any experienced guesses where to look first?

Why do I bother using the tuner instead of running straight to the antenna? Well I tried that too and saw very good signal reports also on 7MHz the same time...

Wishing you all happy holidays and great 2011!

73, Markus OH1KIO

4775. Re: [DrakeRadio] Tuning the TR-4C

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-29 16:43:45 UTC
From: Kris Merschrod
Topic: 4774 Message: 4775

Markus,

My experience with the TR-4any and any Drake T-4any is that the final tuning of the rig is to match the output to the load. So, once tuned into the Dummy load you are "almost there."

I, too, find that on the 75-80 meter band the dip is not so precipitous, but the little dip is there. I usually use the output meter on the tuner to watch the pwr out - that is easier to see (Nice meters on the MN-4s and especially on the MN-4C)

In the case where the ANT Tuner is not used, you then have to re-adjust the settings on the rig for a final match to the antenna. I believe that the Drake tuning is technically a "Pi-Net" and aside from resonance for the frequency you are matching the rig to the impedence of the the dummy load or the antenna. Using and inline wattmeter for max out and SWR is helpful.

When a tuner is used I still find that a bit of fine tuning of the rig is sometimes needed although you would think that it should not be needed.

Markus -

Just about all of the Drake 4 Series transmitters are 'on the edge' when tuning to the bottom end of 80M. They just don't have enough capacitance on the output end of the PiNet, resulting in a poor plate current dip into a 50 ohm load. They need another couple hundred pF, depending upon your antenna impedance. I believe the problem is that there just isn't enough delta-c in the loading cap to hit the high end of the band if there is enough fixed capacitance to cover the low end. Easiest fix is to just add some capacitance across the output connector to get all the way to the bottom of the band. It may be possible to find just the right value to still allow you to hit 3995 if you use both, but I suspect you'll have to switch it out to cover the entire band.

4777. digital displays tr7 & r7.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-29 18:50:08 UTC
From: w1fued@sbcglobal.net
Topic: 4777 Message: 4777

Can someone help with digital display questions?

I have a tr7 that is missing bottom segments on all digits, and an r7 missing the middle segment in one digit (10kc digit)

If one digit is missing a segment or Weak is it the segment or the driver?

If a group of 2 or 3 digits is missing multiple segments, say the bottom segments, is it the digits or the drivers?
Any help as to when the problem is the driver or digit itself?

I have a good display board and it works when the digitial display is moved between radios.

Any help would be appreciated.

4778. dds vfo for tr7 Band information?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2010-12-29 19:39:20 UTC
From: w1fued@sbcglobal.net
Topic: 4778 Message: 4778

I have built a dds vfo from n3zi kits, its really come in handy as a signal generator more than anything else, so far.

I have an old beat up rv-7 vfo thru which I sent the dds vfo signal into the tr7. It works great and has great possibilities, but am still using the digital display on the radio. I really dont use the display on the dds vfo except for initial setting of freq. Using the dds vfo "blind" as the rv-7 does.

Since this vfo has memories (which includes if offsets, I can program the ham freq to read out on the display, but each time changing memories for band changes. I realize this would not be actual freq. display, but merely a "calculated" freq. which might be good enough.

How does the band switch send info to the display? I am looking for a qick and easy way to try this, possibly even doing with 12v to small relays if the band switch supplies some voltage for each band switch setting.
Any thoughts?

Thanks,
W1FU

Hi Peter,

Welcome aboard.
If your TR-3 was used with an RV-3 then a jumper wire was cut between pins 2 and 8 of the RV-3 jack (J2) on the bottom of the rig. That will disable it.

73,
Mike AA8W

>Any help as to when the problem is the driver or digit itself?

One digit missing a segment is a problem with that display segment. More than one digit that has a problem with the same segment is a driver or connection problem. I would look at the soldering on the DR-7 first.

>Any thoughts?

The TR-7 service manual describes it pretty well. The band switch provides a binary divide-by-N preload value to the digital control board that sets the band segment. This number is further manipulated by the UP/DOWN pushbuttons and the DR-7 logic to provide the 500 KHz segments within each band segment. To do what you want to do it looks like you would need to decode the output of U9005/U9006, the programmable up/down counters on the DR-7 (remeber that you are still limited to 500 KHz travel at the PTO freqency).

You will want to read section 1-3.3 and section 4 (the DR-7 addendum) in the service manual to get the picture. There is also some logic to stop the UP/DOWN progression when you reach the edge of a band segment, you could probably bring this out as well to light a big red light to prompt you when you need to change the bandswitch. You still have to deal with the 500 KHz PTO travel, though.

The fun way do do it would be to have the DDS provide the divide-by-N number to the synthesizer. No more UP/DOWN pushing on the radio if the DDS can increment/decrement the N count and roll the PTO frequency back to the other end automatically.

Or, maybe you could just replace the 48.05-78.05 MHz VCO signal entirely with the DDS, if it will go that high. The VCO is phase-locked to the PTO, and it would actually be a simplification of the design to do it all with the DDS (and would probably reduce phase noise in the bargain). The DR-7 could still function as a frequency display, as that part of it is just a frequency counter reading the VCO-1st IF frequecy.

You still need the mechanical banswitch for switching the filter octaves and doing some high-end poodle-faking with the ALC circuit.

I hope this makes sense to you, I'm just winging it here...

Peter,

Here is the advice given to me by a friend when I started restoring my TR-3. He has restored several pieces of ham gear over the years (he has more than 70 tube rcvrs/xmtrs/ xcvrs):

1. Replace the two wire power cord with a 3 wire power cord. Use old pc power cords. Green or Green/Yellow goes directly to chassis. If the unit isn't fused, for example Johnson transmitters had two fuses in the plug that goes into the wall, install a fuse block and fuse in the hot line (black wire).

2. If the rig is more than 40 years old, check all the electrolytic and paper capacitors for leakage and replace any that are bad. Ceramic and mica caps usually don't go bad but there are exceptions, as in micas that have a constant DC voltage across them. The leakage test can be done with a capacitor checker (great instruments) or with a variable high voltage power supply, some resistors and an ammeter. The leakage on any capacitor except electrolytics should be very small (no more than a few uA and preferably unmeasurable). Electrolytics will have great leakage but you should never have more than 1 mA. Leakage in electrolytics is bad as it puts an unnecessary load on the power transformer. Leakage in bypass and coupling caps also puts a slightly increased load on the transformer but the real culprit is leakage into the grid of the next stage from the plate of the preceding stage. This leakage upsets the bias, causing increased plate current and fried resistors and transformers. If the unit is less than 40 years old, just check the electrolytics.

3. Check all the carbon comp resistors and replace any that are more than 10% off. Carbon comp resistors usually drift high, often as much as 200-1000%. Wirewounds don't often change but you should check them anyway.

4. Check all the tubes on a good tester and replace any that are really bad. Don't replace any that are just barely good or even on a tad to the bad side as they may work perfectly. The best tube tester is the unit itself. An actual tube tester is just to get you to first base. Clean all the tube pins and treat them and the tube sockets with a very small amount of Dexoit (www.caig.com). Same thing with the wafer switches. Don't use the spray. Use the liquid.

5. Tighten all screws, specially those that hold a solder lug that is used for ground as the connections tend to oxidize and a bad ground can be horrendous to troubleshoot.

6. Along with the above, give the unit a good cleaning, replace any open/missing lamps and inspect all the wiring for poorly done modification, solder joints, missing insulation, etc.

7. Get a Variac. Bring the rig up on a variac with a 110V 100 Watt lamp in series. If you have any major problems the lamp will light. If it doesn't, remove the lamp and bring the rig up slowly and let it sit for an hour or so.

8. At this point it will probably work but, if it's a receiver, it's likely to need an alignment.

9. If you have scratchy, intermittent potentiometers, dismantle them and clean/lube them with a product from Caig called Fader Lube.

Aren't boat anchors fun?

Bill

Check the ripple on the power supplies. An oscilloscope
is best but an AC voltmeter will do. It sounds like you have
some bad filter caps there, at least a place to start. They
will not only produce hum but also deliver the wrong DC
voltage.

Too bad, I thought I had a quick fix for you:-(
The hum has to be coming from somewhere. If not power
supply ripple then it must be a grounding problem or heater
voltage getting in somewhere. Can you tell if its at the
power line fundamental or second harmonic? That may give you
a clue. I think the AC-4 ripple is at double power line
frequency. I use mine, which has the Heathkit Shop mod in
it, on a T-4XB. It does show ripple when the transmitter is
at full output but is pretty clean at lower demand.
Another trick is to poke around the wiring with an
```

insulated stick, a plastic adjustment wand or something similar. Just wiggle wires around, that will often show up poor solder joints, split resistors and such. Someone else here, Gary likely, may be able to pinpoint the problem.

4787. NEW! Service Supplement CD for R-4A / T-4X

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-01-01 15:30:58 UTC
From: Garey Barrell
Topic: 4693 Message: 4787

I have received numerous requests for a CD covering the R-4A and T-4X.

Here is the "other" one, for the 13 tube (early) version of the R-4A!

Hopefully people have not given up, or the requests were not all from the same person, but ...

This CD is for the 13 tube version of the R-4A (s/n 2000 - 4053). The T-4X was also in a state of
flux, as I have found three distinct versions of the schematic, none dated or otherwise identified.
Of course both R-4A schematics are included, plus all three (now four) T-4X schematics.

There are 61 pages, 35 of which are in high resolution color, in the Service Manual.

The CD for the 11 tube version of the R-4A (s/n 4054 - 6999) is also available. Of course both (now
three) R-4A schematics are included, plus all three (now four) T-4X schematics.

There are 58 pages, 32 of which are in high resolution color, in the Service Manual. Along with the
Manual directory with quality scans of the C-4, L-4B, FS-4, MN-2000, W-4 and other original manuals,
there are the usual batch of miscellaneous files with field changes, modifications, troubleshooting
tips, etc.

The CD for either version (13 or 11 tube) of the R-4A is $25 delivered. Each will also include the
T-4X, and the Manual and Miscellaneous directories.

A combined version, including BOTH R-4A versions plus all T-4X data, will be $45 delivered.

All the previous CDs for the 2-B, 2-C/2-NT, B-Line, C-Line, TR-4 and TR-4C are still available too!

4788. another TR7 demise - help needed

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-01-01 23:17:53 UTC
From: Craig Roberts
Topic: 4778 Message: 4788

I imagine a trip to Jeff's is needed on this one, but, here goes:

My backup TR 7 -- which I have converted cosmetically to a TR 4310 (front panel swap), just stopped transmitting -- sorta.

I get no output on 40 and 20 and a little on 80 with about 50 watts out on 15 and 10.

Things to know:

1) I was running SSB when it failed.

2) When I re-wired the mic connector during the front panel swap, I used a 1K resistor across pins 1 and 4 as mentioned in the literature. The original was a 470 ohm. With the 1K resistor, the mic gain was much more sensitive.

The rig was running without a fan.

What have I fried?

Thanks and 73,

Craig

I almost hate to say it, but... PIN diodes? If you have a scope or an RF probe, you can look to see where you are losing drive - PAs, drivers, predriver, excitern board, etc. I've seen leaky driver transistors cause strange things.

Uh, what? I've never heard of 470 Ohm or 1K there. The references I have seen have always been 470 K Ohms. Is that what you meant, ir is this a "4310 thing"?

Ooops -- I meant 470K, not 470.

This is what lead me to make the substitution (from Ron Baker's website):
>
"The TR7 microphone connector has an internal 1000 ohm resistor between
pins #1 and #4...."

I had a TR7 earlier that had the 1K resistor vs. the 470K, so I wanted
to see what the difference was. I found out.

This is still the first I have heard of the 1K. I would be interested to know where Ron go that info. The service manual does show the 470K. Also, there is an optional (by jumper) 680 Ohms to ground on whatever board it is that houses the mic amp, to match low-impedance mics. I've never actually heard of anyone using it, though. Strange...

The change of operating frequency when you key the mike is your problem. You have to find out what caused that. It sounds like one oscillator is quitting.

But I am no Drake expert.

That sounds almost like a synthesizer unlock condition. This is starting to
sound like the odd anomalies that can happen from dirty/oxidized Molex pin
connectors. Always worth checking.

4795. How much does your drake 4C-series drift?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-01-02 18:50:48 UTC
From: arsnf7z
Topic: 4795 Message: 4795

I've become far too familiar these days with the innards of the PTO on my Drake R4C. it's become an obsession truth be known. everytime I think I have found a solution, my thrill ebbs after a few hours as the dog-gone thing has drifted far out of specification.

specification as I know it to be, and if not, I have defined it as one-hour warmup, drift after warmup not to exceed 100hz. my TR4C and T4XC easily meet this, never driftying more than 100hz from power-on. my R4C drifts about 300hz the first hour, and 150hz/hour after that. the PTO continues to increase in frequency, though the deviation does decline over time.

I have replaced every component in the PTO without success. all my tests are both in the R4C and stand-alone on the bench. my observant wife asks me 'how do you know it ever worked correctly and to specification'. well, I really don't, though I cannot imagine a PTO came out of the Drake factory improperly compensated. that is, these capactiors were hand-selected and most certainly intelligently so.

my first question is to the nature of the capacitors in the tuned-circuit. there was a time when I was young, that you could pull these off the shelf and yet I now cannot remember their characteristics. they are the tubular caps, ~3/4" long and 1/8" hollow diameter. as I recall, they have special temperature coefficients, I would imagine to be positive. can someone please enlighten me?

per my wife's question, what are typical values of drift that are experienced with the R4C? the temps at the R4C PTO are far higher than in the other units where the power supply is not resident. if the PTO drifted 300hz the first hour and then stabilized, I would have no complaints. however, it doesn't stop there.

I would appreciate any observations, guestimates, at what the drift is and what might be considered normal for a tube receiver. oh, and what type of factory-selected capacitors are used?

thank you and 73's

NF7Z, daniel

Topic: 4795 Message: 4796

My R-4C will drift about 500 hz in the first 1.25 hours, then it stabilizes, rather nicely. I notice little or no drift on it, so long as I keep it on, and the house at a fairly constant temperature (+/- 7 degrees, ambient). This is not as good as my R-4B, which seems a bit unusual to me, but the B will do about 300 hz in the first hour, then it stabilizes quite well. Beyond that point, though, is where the C shines. It stays within nearly imperceptible margins, until I turn it off, and allow it to cool down, then back on again. The B will continue a very slow drift, maybe as much as 250-300 hz per day, with the ambient temp being kept within the mentioned margins.
Typically, I do not use the transmitter's VFO for tuning, so I have no notes on them, but now I will have to check that out, once I get my wire back in the air.
I understand that you were asking specifically about the C model, but my notes included the comparison, and thought it would be a good reference point.
Best of luck to you, and I hope someone can give you better information, than I did. But, those are my noted results, in a nutshell, over the past year and a half with the C, and 3 years with the B.
73,
Dan

thanks for the great information Dan. ultimately, I would have to say that over the course of a day my PTO drifts ~1khz from power-on. it might continue on if I let it, though by that time I am depressed enough and turn the rig off!

for those interested, I swapped-out all the tuned-circuit capacitors for standard NPO ceramics with little effect. I even took out some of the components out of a spare RV4C PTO and used them with the same results. bypassed the zener and drove the system from a lab-grade 10.0 volt supply. no change. replaced both transistors. nada. thought I had struck gold when I noticed a half-winding on the coil that wasn't glyptol'd .. no go.

the only thing I can imagine is that the compensation doesn't feedback negative and therefore doesn't work against the drift from heating. as I mentioned, this seems unlikely coming from the factory, nor can I identify a failed component that would cause this issue.

perpelexing for sure ...

I have never kept track of the drift on the R-4, R-4C or TR-4C. 1/2 hour of warm up is about it. While in qso with a group or single OP I am always tweaking the receive on one of the other stations in QSO to be sure that I am on their frequency (using the R-4 for the control VFO).

What I keep hearing from my solid state friends, with their pan-o-graphs, etc, are comments such as "you are 10 Hz low," etc. (Is that the thickness of the red hairline? ":>)

IMHO Drakes are from a different world, and as long as they are not jumping around and off frequency (as opposed to a drift), the quest for precision where precision is not to be had is a distraction from operating.

Happy New Year to all,

I'll agree and in no way am I expecting modern-day synthesized performance and stability from my Drake R4C. to be clear, I am attempting to find why it is not meeting Drake's specification. that is a much different objective.

Daniel

Many times in older pieces of gear the drifting is actually caused by worn band-switches changing in terms of contact as they heat up. This did not occur when the switches were new but over time with aging and use this can be the result. Drake did not use very high quality switches in their gear which again over time results in this problem.

My answer to them would be, "No, you're 10 Hz high!".

I laugh at these guys. I remember when you were in hog heaven if you had 5 KHz dial markings. 1 KHz on the C-line was a absolute luxury. It's all relative. And, not really related to the original question... So, it's been a while since I had the C-line on the air, but I don't recall noticing any excessive drift. FWIW.

Tim,

thanks for taking the time to respond. the interesting thing is that the PTO exhibits identical behaviour in the R4C, and outside it on the lab bench, so it isn't a bandswitch issue. the drift is always positive, drifting higher in frequency, and is not attributable to the 11.0 volt supply or loading, as I once thought.

here are my thoughts, having been a ham since 1961 (I just turned 60). when we were all operating AM, drift was not a huge consideration. when everyone was using equipment with inherent drift, it was accepted that a small amount of drift was normal. this generally meant the QSO migrated up or down the band as everyone attempted to follow the other.

it's perfectly fine with me to have someone mention I'm 10hz too high in a rountable QSO, but otherwise, there is no good reason that adjustments can't be made via receiver tuning or RIT to compensate for the inaccuracies of a bygone era. and frankly, I have no problem moving the tuning knob in a roundtable, net discussion.

I suppose that is why I am enjoying AM and using vacuum tube equipment once again. I am also enjoying taking a thirty-five year old radio and (attempting) bringing it to factory specifications, because I also enjoy SSTV and RTTY where one cannot have such high tolerance to instability.

Hi and thanks for your answers.

A short update about my TR-3. It's working ok in receive now on 80 and 20M and really well too :-)
The OA2 (V20) flickers with some hum on 40 and won't ignite on 15 & 10M.
USB/LSB are working ok. I checked the AC-4, 288 Volt DC without any load with 0,3 Volt ripple, Bias was -51,2 with 0,6 Volt ripple (AC-voltmeter), I haven't checked the HV yet.

All I have done inside the radio so far is cleaning of wafers and tube sockets.
Checked and retightened all ground lugs (I hope) and resolder one resistor.
Any ideas or suggestions about the OA2?

Peter -

A flickering 0A2 sometimes indicates marginal overhead voltage, or a faulty 0A2.....! Measure the voltage on Pin 1 and see if it holds steady near +150 VDC as you change bands. The source resistor that comes directly from the +250 VDC bus is a wirewound, R112, and these don't change value often. They CAN become intermittent, but that's also pretty rare.

The 80 and 20M bands are 'mirrored' from the 9 MHz CO and 5.5 MHz PTO. The other bands are developed via the BAND oscillator, V1, and associated Premixer V3. Swapping out these 6EA8s and/or measuring the voltages around these stages may give a clue.

Just a guess from several thousand miles away would say that something in the V1 and V3 stages are drawing excessive current from the +150V bus when they are switched in.

4808. TR7 ALC light & Power indication

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-01-03 20:58:33 UTC
From: Brenton Crowhurst
Topic: 4803 Message: 4808

Greetings Drakies, and Happy New Years, one and all!

I'm having a puzzling problem--a bit intermittent.

It began yesterday when I turned the rig back on after being away for a week.

First thing I noticed, the S Meter bulb was gone again. Just replaced that a couple months ago. Perhaps it's unrelated to the real problem.

On transmit, the ALC light on the TR7 doesn't illuminate. Out put fluctuates. Testing it with key down in cw mode, it's fluctuating between 10 or 20 (I think) watts and 110 out. As measured by the MN 2700.

I managed an SSB qso yesterday with no ALC light, not realizing how low my power was. Guess I better correct the log book regarding my output power, Hi!

So, the radio seems to work. Except for the lack of power.

Any ideas are greatly appreciated.

Thanks in advance,

Brenton

Hi Garey and thank you,

I guess I know what to tomorrow night then :-)

I'll check the voltage around V1 and V3 tomorrow, did a second check according the resistance chart in the manual tonight, all results was ok I think, slightly high but not much, pin 9 on V1 was 163 KOhm the same at pin 2 on V3 163 KOhm, both should be 150 by the manual.

I have had problems with wire wound resistors
developing bad contacts between the winding and terminals.
They can be intermittant, I had one multisection WW in an
old General Radio generator that oscillated! As it heated up
the contact would open, then it cooled a little and it
closed again. Took me a while to figure out what was going
on, because, of course, it measured good when cold.
Also, VR tubes can filcker and be dim if the minimim
current through them is too low. Try disconnecting whatever
is connected to it and see what happens. VR tubes do go bad
but they are pretty long lived. My bet is on the resistor.

Hi Brent,

That sounds a little bit like what was happening when I had leaky driver transistors on the PA deck. However, first I would check for "connectoritis", intermittent gain pot on the predriver board, or failing T/R relay.

I assume your speaker is connected to the TR-3 through the multi-pin connector at the rear of the TR-3. Try connecting the speaker to the headphone jack instead. If the hum goes away then the problem is poor grounding of the speaker wire inside the TR-3.

Garey

Measured the voltage on OA2 (V20) under load today.

80M 148,9 VDC
40M 150,1 VDC
20M 149,0 VDC
15M 150,0 VDC

On 10M it was unstable, from 138 to 150 VDC,
finally it stabilized around 150 there too.
No visible light inside on 15 and 10M.

Richard

Did a double, even a triple check on the two
wirewound resistors R110 and R112, found a really
bad solderjoint on R112, eletrically it measured ok but
it might be a source for problems. Resoldered it.
Thanks for info!

4814. TR-4C neutralization

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-01-06 02:04:25 UTC
From: William Houghton
Topic: 4814 Message: 4814

Hi fellow Drake fans.

It's been some time since I last worked on this but I could never quite get the finals neutralized in my TR-4C. I followed the instructions in the manual. I could never quite get to the point where max RF out corresponded to min plate current.

Is this a tough adjustment to make, or am I having a mental lapse every time I try to do this? Are there any methods other than what is described in the TR-4C manual to achieve this? Is my IO-10 monitor scope of any help in this process?

I haven't worked on this for abour 6 months and would like to give it another shot.

73,

Bill

Bill -

Are all three tubes from the same manufacturer? Different brands don't all neutralize at the same capacitance, (some not all,) which can make it difficult.

If they ARE all the same, try neutralizing on 15M first. The 'sweet spot' is a little bigger on 15 than on 10, and a little easier to find. Once you get it on 15, then only a tiny nudge to refine for 10.

The 'classic' neutralization procedure is to turn the amplifier (transceiver) OFF, feed a small signal INTO the OUTPUT of the amp, peak the TUNE and LOAD controls for maximum signal level at the INPUT of the amplifier stage, and then tune the neutralization cap for minimum signal at the INPUT side. Monitor the input with receiver or other sensitive detector.

The Drake method is easier, especially after you do it a time or three. It just takes patience. Do as they say, carefully dip the PLATE current well below 200 mA, which should give you a nice sharp dip. Then, watching the output POWER meter, turn the PLATE control either way from the dip point. If the OUTPUT power goes down, then carefully re-dip and then turn the PLATE control the 'other' way out of the dip. If the OUTPUT power goes down again, you're done! If the output power goes UP in either direction, adjust the neutralization cap slightly one way or the other and try again! I guess it helps to keep track of which way, but after you do it a couple of times you can tell if you made it better or worse with the neutralization cap adjustment and try it again. AGAIN, it's easier to find the spot on 15 or even 20M since it's broader as you go lower in frequency. Once you get it on the lower band, it takes only a tiny adjustment to refine it on 10, which is the sharpest null.

Thanks Gary.

Yes, they are all Sylvania tubes.

You feed in a singal into the output with an RF generator? Can you monitor the input with a scope ?

Bill

Subject: Re: [DrakeRadio] TR-4C neutralization

Bill -

Are all three tubes from the same manufacturer? Different brands don't all neutralize at the same capacitance, (some not all,) which can make it difficult.

If they ARE all the same, try neutralizing on 15M first. The 'sweet spot' is a little bigger on 15 than on 10, and a little easier to find. Once you get it on 15, then only a tiny nudge to refine for 10.

The 'classic' neutralization procedure is to turn the amplifier (transceiver) OFF, feed a small signal INTO the OUTPUT of the amp, peak the TUNE and LOAD controls for maximum signal level at the INPUT of the amplifier stage, and then tune the neutralization cap for minimum signal at the INPUT side. Monitor the input with receiver or other sensitive detector.

The Drake method is easier, especially after you do it a time or three. It just takes patience. Do as they say, carefully dip the PLATE current well below 200 mA, which should give you a nice sharp dip. Then, watching the output POWER meter, turn the PLATE control either way from the dip point. If the OUTPUT power goes down, then carefully re-dip and then turn the PLATE control the 'other' way out of the dip. If the OUTPUT power goes down again, you're done! If the output power goes UP in either direction, adjust the neutralization cap slightly one way or the other and try again! I guess it helps to keep track of which way, but after you do it a couple of times you can tell if you made it better or worse with the neutralization cap adjustment and try it again. AGAIN, it's easier to find the spot on 15 or even 20M since it's broader as you go lower in frequency. Once you get it on the lower band, it takes only a tiny adjustment to refine it on 10, which is the sharpest null.

Bill -

No need to monitor the input to the output of the amplifier with a scope. All you need is enough signal to be able to detect it at the input of the amp with a receiver.

Neutralization means that you are coupling (via the neutralization capacitor) from the OUTPUT to the INPUT of the amp enough _negative feedback_ (out of phase signal) to offset the capacitive coupling from the INPUT to the OUTPUT through the PA tubes. Essentially the neutralization capacitor is equal in value to the interelement capacity of the three tubes. This is why some tubes won't neutralize without adding additional fixed capacitance across the neutralization trimmer.

So with power OFF and disconnected from the AC-4, connect your separate receiver Antenna via a coax lead clipped to the Plate of V6. Then apply the signal generator to the transceiver Antenna connector, find the signal on the separate receiver, and peak with the TUNE and LOAD controls on the transceiver. Adjust the neutralization capacitor on the transceiver for minimum signal at the receiver and you're done.

Thanks Gary ! About a month or so ago I picked up an older Heathkit tube type "lab" RF gen (the one with the meter on it) for $20. This will give me a chance to use it. I can use my Icom 730 or my R-4A as the receiver.

4819. Looking for additional Frequency Counter for my TR-7

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-01-06 21:46:02 UTC
From: Hans-Joachim Empel
Topic: 4819 Message: 4819

Hello to the Group ,

i am looking for an additional frequency counter for my TR-7.

Has anybody an idear what kind of Frequency Counter i can use ?????

If anybody has an idear for buying a counter , please let me know.

All Informations are welcome.

Kind regards from Germany

Joachim Empel

I am setting up the TR-7 in the front of my shag , the RV7 Unit and the
Speaker a little bit away from the TX.

The Problem is : i cant see the Frequency of the TR-7 in tis conditions.

Thats the reason that i am looking for an additional Frequency Counter.

73,
Joachim

You would need a preset counter that can handle the offset of the L.O., and a buffer amplifier for the L.O. to feed it out to the external counter.

From: Garey Barrell
Topic: 4819 Message: 4824

OK. I assume you can't arrange to sit in front of the TR-7 for space reasons.... If I understand correctly, you are using the RV-7 as a 'remote' control.

I don't know of any specific units designed for this service. You have two choices that I see; 1. A plain frequency counter that is able to sample directly the output of the transmitter, or , 2. A 'special' counter that monitors the RV-7 and has a reference oscillator to compensate for the offset of the mixing scheme.

AADE <http://www.aade.com/dfd1.htm> offers a series of both types of counters, but I don't know if his units can deal with the VHF IF of the TR-7.

Another possible source would be the N3ZI kits at <http://www.pongrance.com/> for either direct or indirect measurement.

Certainly a simple counter would be the easiest to implement, all you need is a way to sample a small portion of the transmitter output with a capacitively coupled "T" or other 'sniffer' arrangement.

Thanks for the Informations , i will contakt AADE and N3ZI , but i think the easiest way is to use
the simple methode with a counter and a coupled " T ".
I think i need an smal amplifier to hold the signal stable , but the next days iwill spend some time to check this out.

Thanks for all this helpfull Informations

Kind regards and 73

Joachim

Thinking about this a little more, since the DR-7 display is a preset counter reading the L.O., it should already have the buffering you need. You could probably pick the buffered L.O. off of the DR-7 board to feed directly to an external preset counter. The digital dial adapters marketed for use with vintage radios are usually preset counter designs with programmable offset to allow for various different IF frequencies.

Garey,

I thought I once read something you wrote that said you have used a grid dip meter for neutralization. Are you using the GDM as the signal source?

Bill

Subject: Re: [DrakeRadio] TR-4C neutralization

Bill -

No need to monitor the input to the output of the amplifier with a scope. All you need is enough signal to be able to detect it at the input of the amp with a receiver.

Neutralization means that you are coupling (via the neutralization capacitor) from the OUTPUT to the INPUT of the amp enough _negative feedback_ (out of phase signal) to offset the capacitive coupling from the INPUT to the OUTPUT through the PA tubes. Essentially the neutralization capacitor is equal in value to the interelement capacity of the three tubes. This is why some tubes won't neutralize without adding additional fixed capacitance across the neutralization trimmer.

So with power OFF and disconnected from the AC-4, connect your separate receiver Antenna via a coax lead clipped to the Plate of V6. Then apply the signal generator to the transceiver Antenna connector, find the signal on the separate receiver, and peak with the TUNE and LOAD controls on the transceiver. Adjust the neutralization capacitor on the transceiver for minimum signal at the receiver and you're done.

Nope, wasn't me. You need a generator with a shielded output cable as
you need to minimize coupling the signal AROUND the amplifier.

Very few GD meters are stable enough anyway! :-) A modern, SS
transceiver is a good signal generator if you are VERY careful to limit
the output. One way is to put a "T" connector on a dummy load, with the
power turned all the way down on the transceiver, but you have to
proceed with great caution. Not TOO much danger since you are feeding
it into the output of the amplifier you are testing, and you shouldn't
have enough fed back through even with with no neutralization to harm
the detecting receiver, but you can't be too careful.

4830. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-01-09 19:59:28 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 4830

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

FOR SALE - Various Radio Items:

Hallicrafters Sky Buddy S19, Excellent - $165.00

Yaesu FT-101E, may need some work - $225.00

KLM ECHO 70 SSB-CW Transceiver for UHF 70cm Band - $95.00

RL Drake Company receiver 100 kHz - 30.0 MHz PRN1000 - $145.00

Two 250 watt variacs - Each designed for 0 - 250 V AC at 1 amp.
Can be used at 120V AC also.
Available for $27.00 each

Heath HD-15 Phone Patch - cherry, $15.00

Panel meter - 0 to 200 mA DC, 2" diameter with hardware - $5.00

Group of variable capacitors -
Consists of TWO DUAL 500pf air variable capacitors and TWO 350 pF
single air variable capacitors.
ALL FOUR for a total of $20.00 plus shipping.

MFJ-760 notch filter - 80 to 180 MHz... $4.00

Hamtronics 800 MHz receiving converter $4.00

14V DC at 4.5 Amps power supply.
AC operated supply. Based on a circuit Board. Rugged design - great
for filaments or for use with other projects. Excellent working condition.
QTY 1 available for $8.00 plus shipping.

More parts and accessory items will be added soon...

From: Dave Drake
Topic: 4835 Message: 4835

To the Group,

It probably needs to be communicated from time to time a few web sites that have great information on RL Drake products, service and parts. Lots of history too, like pictures and manuals and rig descriptions. Within each of these sites are links to many other websites.

And yes, the Drake feet you see on ebay, and elsewhere are near carbon copies of the originals. The even come with the little stacking screw to create an improved viewing angle.

Anyway, Here they are:

www.wb4hfn.com Click on the Drake logo and you'll get to the drake portion of the site. Lots of service information and many helpfull and informative articles Drake collectors and technicians. Ron Baker, who owns the site also does service work on Drake rigs and does sell a few Drake items to help keep the site going. As well, there is also listed other technicians who work on Drake gear. Here's a quicker link to parts and service:
http://www.wb4hfn.com/DRAKE/DrakePartsService.htm
and an even quicker link to a more specific page put together by Mark Gilger:
http://www.wb4hfn.com/DRAKE/DrakeArticles/TechTips/Drake-Tech-Exchange-17.pdf Its a pdf file that can be printed out easily and used for future reference. Several links on it as well.

http://k4oah.com/ Service CD's for several of the tube type drake radios. Excellent product by Garey Barrell.

http://www.df4nw.de/ If you need a replacement display for a TR7, this is the only one I know of. I have one and its works great.

http://www.dproducts.be/DRAKE_MUSEUM/ Scroll down to the "source" tab on the left and you'll find quite a bit of parts source information. Do click on the other tabs and enjoy this great website.

Mike,
Do you have manuals for the L7 and TR7 shown in the photo on your QRZ page?? That will show us if you have the information for proper hookup. Are you trying to use the L7 with the TR7 or the rice box in the photo?? That also gives needed information. You should try NO poking around in the interior with no linear experience. Dangerous, life threatening voltages are inside!!!! The person that "upgraded" your amp really should have given you assurance that it works, and your step by step tuneup instructions, but give us some more information and some of the "guru's" on here will help. It's not me, unfortunately, but I do "use" a Drake amp, hi.

4840. AC4 Tranni

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-01-18 09:22:17 UTC
From: Victor
Topic: 4840 Message: 4840

Hello all
Regret to say that the tranni has gone in my AC4 and I don't hold out much hope in sourcing a replacement. I have another PSU from a tube Tx that might fit the bill. The output voltages are the same except that the EHT is 750v. The other thing is that I don't think that the filament winding would be robust enough having been designed for only one P.A. So, if I parallel up a 12v 5amp tranni with the LT winding would that be OK? Also, would 750v overtax the PA's and associated ccts?

Don,
Thanks for the heads-up! I did hook it up to the TR7 as illustrated by my Manual and I really don't want to go poking around the interior of the "Widow maker". And it is NOT hooked up to the rice box!(grin)

Before I sent the L7 off for mods/upgrades, the tubes did glow on transmit...but not very long, there was a circuit that went bad and was repaired, I was wondering if during transit back to my QTH that the L7 did't get bumped, I had read that the tubes need to be out during transit, but also read these tubes are really robust during operation.

> Do you have manuals for the L7 and TR7 shown in the photo on your QRZ page?? That will show us if you have the information for proper hookup. Are you trying to use the L7 with the TR7 or the rice box in the photo?? That also gives needed information. You should try NO poking around in the interior with no linear experience. Dangerous, life threatening voltages are inside!!!! The person that "upgraded" your amp really should have given you assurance that it works, and your step by step tuneup instructions, but give us some more information and some of the "guru's" on here will help. It's not me, unfortunately, but I do "use" a Drake amp, hi.

George,
Thanks for the return! I have tried it in Standby and Transmit, no effect of key clicks! You could be on to something! I do have the rig connected as illustrated in my TR7/L7 manuals.

Date: 2011-01-22 20:41:54 UTC
From: Bry Carling
Topic: 4845 Message: 4845

FOR SALE:

More homebrew parts delight...
A group of 8 unusual tube sockets and one male plug.
Most of these appear to be for compactron tubes as noted.

All are new and unused except one.

Two 12-pin sockets - new
One 11-pin socket - new
One 11-pin plug - new
One 11-pin socket - used
Two 9-pin sockets, new (one missing a pin, easily replaced from
a smaller donor socket)

One larger vented socket, sems to be a 4X150A style socket.

I don't want to ship these out separately, so will sell the entire group
for $24.00 plus shipping.

Topic: 206 Message: 4846

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

Hi everyone

A follow up on my TR3. It's working fine now, turned out that
C3 100uF in my AC4 was bad, voltage dropped in the 250V line
to under 220V under load, on higher bands 15, 10 and on 40 even as
low as 216V. Replaced it and now a stable 250V. I'm going to replace
the others to to be on the safe side.

I really enjoy listening to my TR3, it's a fine radio.

Thanks for all the help and hope to hear you on the bands.

4853. FS: Unique Drake Service Supplement CDs

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-29 22:32:21 UTC
From: Garey Barrell
Topic: 993 Message: 4853

Here is the information that Drake left out of their manuals!

Unique supplemental service information CDs available for the Drake TR-4, TR-4C/Cw/CwRIT, A, B and C
Lines, 2-C / 2-NT and the 2-B receiver.

High resolution color photos of the under chassis and individual PC boards of each unit, with all
parts identified and keyed to a parts list make it easy to locate any component. No more trying to
trace wires through bundles, etc. This information is not available elsewhere and really makes a
difference in servicing these units.

These CDs are NOT just scans of the original manuals that were included with the equipment when new.
High resolution scans of the original manuals ARE on the CDs, along with scans of manuals for
associated equipment such as the C-4, FS-4, MN2000, L-4B, W-4, etc.

Samples of these pages (at reduced resolution) and purchase information are at <www.k4oah.com>.

4854. Another TR7 implosion

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-01 19:34:29 UTC
From: Craig Roberts
Topic: 4837 Message: 4854

I bought an extra TR7 as a backup, just in case...

Well, now BOTH of them are out of commission. Grrrr.

The latest failure went like this:

1. During a normal transmission, the display went haywire. I unkeyed the rig and cycled the RCT switch (which had seemed a little flaky lately, even though it had been thoroughly cleaned recently).

2. I keyed the rig again. The output meter pegged. I backed off the output to zero and keyed again. The ALC LED lit and the meter pegged again (there was no ALC action at all). I detected the unmistakable smell of a frying resistor and shut down the rig.

I have yet to find the charred component, but I haven't had the radio apart yet. The smell seems to be centered around the ALC board or final amp brick. This radio has been thoroughly serviced twice in the last year and appears never to have been abused. (In fact, it looks near new inside and out).

Whaddya think? (My other radio doesn't transmit, either -- but its failure seems more like a driver or PIN diode problem).

I love my TR7s but, I gotta tell ya, this is getting very frustrating.

73,
Craig

I've been pondering this. It almost seems like you have multiple different problems. The display problem suggests intermittent Molex connectors, or perhaps the DC-DC converter power supply or a different power problem of some sort. The pegged meter sounds like PA deck oscillation. The burned smell, maybe PIN diodes or the aforementioned DC-DC power suppy. All areas to look at.

In the past, it seems that a lot of strange 7-line problems can be cured by pulling all of the PC boards one at a time, cleaning and DeOxiting the Molex connectors (check the female connectors for tension too), and re-seating. Also, failure of the large filter cap on the DC-DC power supply board can cause strange problems. Replace it with a modern 105C temperature rated cap as preventative maintenance while you have the rig apart. PA deck oscillation can be caused by excessive predriver gain, but this usually only shows up on the 40 Meter band segment; I've also seen leaky driver transistors cause it. Check the base voltage on the driver transistors in RX, it should be 0 volts. If it's anything even remotely approaching 0.6, you have leakage. The PA deck can be removed as a unit, without disconnecting any wires, and set on top of the radio by removing four screws on the right side of the rig. Check the PIN diodes as well, there are procedures on wb4hfn.com and the Drakelist web site.

I hope this helps.

4856. Re: Another TR7 implosion

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-02 14:10:25 UTC
From: Dave Drake
Topic: 4837 Message: 4856

Craig,
First question: Do you have a service manual?

If you do, even the original version, (there were two), find the traces on the motherboard that are 10v lines and check to see if the rig has proper voltage. Also then check the other traces for proper voltage in both rx and tx.

On the PA brick, make sure the predriver is backed off of maximum a bit. If it is at max, then you may have another problem lurking. Yes, pin diodes can be a problem and are very difficult to get to. It would be best to leave that to someone experienced at replaceing them.

My experience is like Jims, that the very first thing to do when you receive your new/old TR7 is to remove every board and clean contacts. Also clean the molex connectors on all plugs. Once you have done this, you can then reasonably trouble shoot any real problems. However, it all starts from the power supply board. Jim is also correct with the capacitor on the power supply board. The PS7 does not provide very clean DC, and the power supply board finishes the job. Thats the way Drake designed it.

I would suggest if you do not have a service manual, you try to obtain one to go much further. If you are not inclined to really dig in, then I would suggest you send the rig (s) to a good Drake service man to repair and get up and running. There are several listed on Ron's website (wb4hfn) as well as Ron himself. A couple more over around the Dayton area/SW Ohio. Jeff Covelli up near Clevelend. I will say if you send it to any of these guys they'll stand behind their work and provide phone support to help you out of any further issues.

Aligned properly, a TR7 is still an excellent ham radio both in receive quality and transmit audio quality. I am continually amazed at how it compares to newer radios such as a TT Omni VII and Icom 7200 (at my location in daily use).

Good luck,
David

4857. Re: Another TR7 implosion

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-02 17:07:09 UTC
From: Craig Roberts
Topic: 4837 Message: 4857

Many thanks to Jim and Dave for their suggestions. I have the afternoon off today - a real rarity -- so I will dig into the rig a bit. (I do have a service manual).

This radio's been repaired by Jeff a couple of times for transmit problems; once just before I bought the radio a couple of years ago and once about six months ago. The last service included PIN diode replacement and a new T/R relay (which, in fact, was the needed repair). Jeff's performed his usual beautiful service and I am confident that the Molex connectors are clean. Neverthless, I do pull and re-seat the boards periodically "just in case."

I removed the power supply board last night and -- by golly -- I think the 220 uf electrolytic is the component that fried. It is not charred, but the overheated smell seems to be coming from it. Anyone who's experienced burned components knows that the unmistakable odor tends to permeate everything around it and is surprisingly hard to pinpoint -- though resistors that burst into flame are easier to find :-) .

Anyway, I'll be replacing that cap go from there with voltage measurements, etc, as needed.

This particular TR7 is in such beautiful shape that it's misleading. I keep forgetting that's it is over 30 years old and -- naturally -- prone to breakdowns from time to time.

I'll keep y'all posted.

Thanks again.

73,

Craig
W3CRR

4858. Re: [DrakeRadio] Another TR7 implosion

From: Craig Roberts
Topic: 4837 Message: 4858

Some progress and a new mystery.

Replacement of the 22 uf electrolytic on the power supply board indeed fixed the display problem. The radio has awakened from the dead and it now receives normally. (I did adjust the power supply board voltages).

However, when the transmitter is keyed into a dummy load now, it acts as if it's working into an open circuit. Forward and reflected powers indicate identically, there's no ALC indication and no output.

Hmmmm. Where do I go from here?

Thanks again,

Craig

4862. 60 Hz hum on 2-B

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-03 03:43:48 UTC
From: randyinaura
Topic: 4862 Message: 4862

When I plug in headphones (8 Ohm) to my Drake 2-B and turn the volume or RF gain way down, I hear 60 cycle hum. No hum is heard through the speaker when the headphones are not plugged in. Is this due to the fact that the headphones bandwidth is too wide, ie. to much low frequency response compared to the speaker in the 2-BQ? The specs on these headphones (Kenwood HS-5) list the low frequency -6dB point at 150 Hz. What's going on here?

4863. Re: [DrakeRadio] 60 Hz hum on 2-B

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-03 04:00:47 UTC
From: Garey Barrell
Topic: 4862 Message: 4863

Those phones have extended low frequency response, AND they are far more sensitive than the speaker.

The AF amp in the 2-B runs 'wide open' gain, as do most receivers. The volume is controlled by adjusting the amount of audio to the input with the AF GAIN control. There is a certain amount of hum and noise inherent in any amplifier, so if you set the AF GAIN to about 10 o'clock you have a specific signal to noise ratio. This provides typical listening volume for a speaker.

Now, if you connect phones instead of the speaker, the phones are much more sensitive, (i.e., generate higher sound pressure for a given amount of signal applied,) requiring that you reduce the AF GAIN close to minimum to prevent blowing out your ears! Again, the hum and noise are constant and you have just reduced the signal, so the signal to noise ratio is worse and yet the phones still provide plenty of audio at the reduced AF GAIN setting.

So if the phones cause you to run the AF GAIN control near minimum, you'll hear that poorer s/n ratio. Easiest fix is to put a resistor in series with the headphone jack that requires you to turn the AF GAIN up to about 10 o'clock or a little more for comfortable listening level with the phones.

I am not familiar with the 2B but I had a similar
problem on a Collins R-388/52J-3 receiver. _60_ hz hum, not
120Hz from the speaker (faint) and quite strong on low
impedance headphones. It was there even when the rectifier
tube was pulled out. After chasing some false leads I
discovered that the frame of the headphone jack was being
used as a ground return for something (never figured out
what). The panel had probably been repainted, at any rate
there was enough paint on the back and front to prevent the
frame from making good contact. The audio return was OK but
the AC being grounded at the frame was imposed on the audio.
Scraping the paint away at the back of the connector fixed
it as would have a toothed lockwasher there. My bet is that
the hum is there on the speaker too but much weaker than on
the phones. Try putting your ear right up against the
speaker. The cause is probably a bad ground return
somewhere. The general advice given for all older Drake
stuff (and many other rigs too) is to work all the screws
that might be used for making a ground return. That will
include all screws holding tube sockets, terminal strips,
printed circuit boards, etc. If that doesn't fix it try
wiggling wires, there may be a cold solder joint somewhere.
If the RX has a half-wave rectifier in it, to provide
bias for instance, check that because it _can_ produce 60hz
hum where a full wave rectifier or full wave bridge will
generate only 120hz and even harmonics.

Hmmm, that's an odd one. I would check Q307 and Q307, the +10 T and R switch transistors on the TX Exciter board.

I'm starting to feel like I'm the only one on this group.... :)

Just an FYI, don't forget to make sure you have all correct voltages on the mother board, not just 10v trace.

Also, if the 10v line was off by very much, say a few tenths of a volt either way, you may need a full realignment !! The radio is very sensitive (in how well it functions and behaves) to the 10v circuit adjustment.

Its critical that voltages on all the motherboard traces are behaving properly in both transmit and receive.

If Jeff did work on the rig recently, just give him a call on the land line. I know he'll help you sort it out over the phone if possible.

Anyway,.....voltages on the motherboard....start there.

Garey,

Great idea. I forgot to mention that this effect is also present in my R-4A and in a Kenwood R-5000 but to a lesser extent. Maybe I should wire the resistor inside the headphone plug, especially if I can find a value that will work for all my receivers. Speaking of value, for the 2-B, to get me started, what decade are we talking? 10ohms, 100ohms, 1K?

Thanks for your help.

Richard,

Thanks for your help. You're right in that there is some hum coming out of the speaker, but you have to be right on top of it and even at that it's barely detectable. At a comfortable listening position, one can't hear any hum. I think the fact that the audio amp runs wide open has as much to do with the problem than anything. This fact was pointed out by Garey in another reply to this thread. I'm going to try his suggestion of a series resistor to essentially make the headphones a higher impedance. Since the hum volume is constant independent of volume control level, I'll have to turn up the volume with the resistor in the circuit and that should take care of the problem. Thanks again for your input. Maybe it's time to follow your suggestions and perhaps even recap the power supply.

Crit -

Not to me..... Depends upon what you want/need. If you need 1000 memories and need to scan them fast... Or if you need 'selectable' sideband synchronous detector for AM as opposed to what appears to be the same thing as in the "A". The description and specs appear identical to me.....

The best value for me is the "A".

Per Bill Frost>>

The differences between the R-8 and the R-8A and/or R-8B are as follows:

1. Mode and bandwidth can be selected with a single button press.
Programmable auto selection of the bandwidth when changing mode.

2. The dynamic range has been improved to 100 db.

3. The third order intercept point has been improved to +20dBm.

4. The frequency stability is ? 5ppm over -10 to +50 deg. C range.

5. 440 memories locations

6. Memory channels scan at about 40 channels per second.

7. A seven digit program name can be displayed on the front panel, Alphanumeric display.

8. The display and entry of frequencies can be made in kHz or MHz.

9. Front panel tilt uses a metal bail.

10. The time display can be programmed to remain on all the time. The R-8A has two event timers.

11. Expanded RS-232 control.

12. Improved AGC

13. A highpass audio filter has been added in the FM mode to reduce sub-audible tone squelch signals

14. Detachable power line cord.

The differences between the R-8A and the R-8B are as follows:

1. Selectable sideband synchronous detector

2. Faster scan

3. 1000 memories

I dunno, you're forming a voltage divider between the series resistor
and the 8 ohm phones so it's dependent upon the SPL (Sound Pressure
Level) or sensitivity of the phones. I'd start with a 1000 ohm! :-)
If you have a 10k or 100k or ... pot, clip lead it in place and adjust....

More modern receivers seem to be less susceptible to this, perhaps
designed for lo-Z phones, reducing AF gain at the PHONES jack, or ... ??

Let us know what value works!

There is a substantial difference between the 8 and the A -- in both circuit and convenience. I had an 8, thought the difference in price warranted upgrading to the A, which I did. I haven't regretted that. I recently had a chance to try a friend's 8 and I am ever more convinced that the small difference in price between the 8 and A (usually less than $150.00) makes the A worthwhile.

There were not so many changes between the A and B (mainly selectable sideband sync tuning, if I remember correctly) and the B sells for about double what a nice A sells for. I have never understood that and certainly have not been the least bit tempted to "upgrade".

Don -

I've never done a direct comparison, but I have an R-7 and an R-8A on my desk. A 'non-technical' opinion is that the '7 is the 'better' receiver for communications purposes. The '7 does have a 'synchro-phase' detector for AM which is essentially an Exalted Carrier, SSB system that appears to have preceded the 'synchronous' system.

Personally, I like the knobs and buttons on the '7 much better than the 'menu', 'multi-push' buttons of the '8. There are eleven double-function buttons with a twelfth 'shift' in the number pad, plus another six double/function buttons for controlling which VFO, Preamp or Antenna, AGC NB, Timer/Step, Clk/Freq / Lock. I admit that I have trouble every time I try to change something and end up in Memory mode or ... I 'really' don't like menus or "push this button and then push this one twice within five seconds." :-)

If you want remote control via RS-232, 440 memories, scanning capability then the '8A is for you. Mine sits on the desk and spends most all it's time on the AM radio band. To get on the air, I turn on the R-7 and TR-7 underneath it!

Hi Andrew

I have a TR-3 schematic that I can have copied. This is for up to serial 1451A and has a number of 1018933001 on the page (not sure what that matches). I would have this put on an 11" x 17" page.

The serial should be located on the back lower left side of the chassis. The serial is a stamped on number.

When you have hum that is independent of the volume control it is often power supply ripple. Check the power supply ripple on the output transformer with a scope.

If may just be a bad filter capacitor.

At a comfortable listening position, one can't hear any hum. I think the fact that the audio amp runs wide open has as much to do with the problem than anything. This fact was pointed out by Garey in another reply to this thread. I'm going to try his suggestion of a series resistor to essentially make the headphones a higher impedance. Since the hum volume is constant independent of volume control level, I'll have to turn up the volume with the resistor in the circuit and that should take care of the problem. Thanks again for your input. Maybe it's time to follow your suggestions and perhaps even recap the power supply.

If the RX is the same as my R4BX the headphone jack is
connected directly across the speaker leads, that means its
an 8 or is it 4 ohm output. In fact you can connect a
speaker there. Most old type phones had impedances of from
about 600 ohms for many military types to anywhere from
about 8K to 25K for magnetic types. While the high impedance
give them high sensitivity when used for crystal sets and
similar high impedance sources it gives low sensitivity when
connected to a speaker terminal. Modern Hi-Hi phones usually
have impedances close to speaker impedance, that is anywhere
from 8 to maybe 50 ohms so they have much greater output
than the old type phones.
You can pad down the output by putting the phones on a
series resistor similar to the impedance of old type phones,
say 10K. Or make an L pad with an 8 ohm resistor across the
jack and a series resistor of whatever value results in a
comfortable level, maybe anywhere from 2k to 10k.
Now, having said that, check the nature of the hum. If
its truely 60hz and not 120hz its more likely to be a hum

loop from the heater supply than power supply ripple. Where a full wave rectifier is used the hum ripple is 120hz. If its 120hz then it could be bad filter caps but that depends on the ripple level at the supply. If its 60hz then look around for bad grounds.
I can use low impedance phones on my R-4B without noticable hum. Your RX may be different but I would poke around tightening screws etc as I suggested. It may be that you can get the hum to disappear. If not, or if others with the same receiver say its normal, than pad the phones.

I forgot to say that 60hz hum can also come from a
heater to cathode leak in a tube. This will NOT show up on
tube testers, it can be found by substituting another tube.
Its not a very likely cause but easy enough to eliminate.

Garey,

I used a 2.5K pot for my initial test. The signal to hum settles down nicely with 250 - 500 ohms in series. That results in a volume control setting of 10:00 to 12:00 for comfortable. I had a 310 ohm 1/4w resistor in the junk box, so I used that. It fit right in the headphone plug. It works just fine now. It also eliminates this problem on my R-4X as well. Thanks for the tip.

Maybe it's time to recap these old receivers of mine. They are still all original. Oh well, problem solved for now.

Randy -

Great! Always nice when it's an easy fix.... :-)

Re your cap replacement. Here is a reply I just sent over on the Drakelist a little while ago.

>>>>>>>>
You'll get two sides (maybe more!) on this. The FACTS are ...

Electrolytic capacitors have a finite lifetime. Various sources give widely different _estimates_ of what this time 'is', and typically settle around 10 years in _typical_ environmental conditions, whatever those are. The cap has a paste that forms the dielectric, which contains water. Over time, this water evaporates resulting in a loss of insulating capabilities and/or capacity. Heat of course speeds up this evaporation, and depending upon how much stuff is piled on top of the radio, it can get pretty hot.

There are four main 'failure' conditions for an electrolytic. One is that the capacitance decreases considerably, another is that a 'series resistance' (presents as a resistor in series with the capacitor), another is it becomes 'open', usually as a result of a corroded internal lead, or, it just shorts out completely. All but the last one causes the power supply ripple to increase, (HUM,) and if the last one does happen, hopefully the power supply fuse will blow before the power transformer is destroyed! This last one is why the FIRST thing I do with a 'new' piece of vintage gear is check the fuse. I have found everything from the correct fuse, to a piece of #8 copper wire....

So obviously all of our Drake gear is on borrowed time if it has the original power supply caps. They may work for another ten years, or they may short out today. The choice is yours, 'do you feel lucky?', or are you a belt and suspenders kind of guy? If you feel lucky, just make sure the fuse is the RIGHT one. If B & S, check with Tom at hayseedhamfest.com. He has Twist-Lok caps that are a drop-in replacement and offers a complete kit that replaces ALL electrolytics in the various Drake radios.

Electrolytic caps won't last forever but the life seems
to vary over a very large range. I have equipment with caps
that are fifty years old and are still good, others fail
after only a few years. The difference is due partly to the
type and construction of the cap, and ambient temperature is
important, they don't like heat.
All capacitors have both series and parallel
resistance. While ESR or equivalent series resistance has
become a popular thing to test for parallel resistance may
be more important for electrolytics. Its also important for
any capacitor used for DC blocking, for instance coupling
caps in audio circuits. Parallel resistance is a measure of
how much DC the cap passes. Ideally, a capacitor should have
infinite parallel resistance but in practice they don't.
Parallel resistance generally will not show an indication on
conventional bridges and capacitance meters even when they

do measure series resistance. One way to measure parallel capacitance is to check the current throught the capacitor on a DC source. To do this you need a DC power supply, preferably an adjustable one, capable of delivering a voltage close to the operating voltage of the capacitor, although a valid reading can be gotten at a lower voltage. You also need a current meter capable of indicating micro-amps. The current from parallel resistance is also called leakage current.
A good plastic film cap should have such low leakage current that it will not even indicate on a sensitive meter. Old paper type caps should have about 5 micro-amps maximum. A good electrolytic with well-formed electrodes should meausure less than about 15 uA. In general, the leakage should trend down with time when a cap that has not recently been used is tested. That's because the electrodes are still forming. There are complex actions going on in most types of dielectrics that can cause the leakage reading to vary with time. It may take several minutes to obtain a final reading. A capacitor that measures good on a bridge where the dissipation factor (or ESR or Power Factor) is within limits may still be bad because the parallel resistance is not mesureed. Even when biased the reading may be false so its really necessry to measure the leakage either as current or on a device that measurers it as resistance (like a megger if the voltage is within the limits of the capacitor).
Some electrolytic caps drop in capacitance. This is due to the fact that one electrode is formed chemically. If the cap has not been used for some time this electrode tends to disappear. Sometimes operating the cap will re-form the plate, sometimes not. The other failure is developing such high leakage taht the cap is essentially shorted. That can be calamitous because it can burn out transformers, etc, if they are not protected. Running a power supply with a vacuum tube rectifier up on a Variac may not protect it because the filament of the rectfier has to reach a fairly high temperature before the tube begins to conduct and by that time it may be too late. The caps just have to be tested out of circuit if one is suspicious of them.

4885. T4XC no output

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-05 18:43:21 UTC
From: K4GM- George
Topic: 4885 Message: 4885

I turned on my trusty T-4XC a little while ago and it failed me! I will try to swap out a tube or two but here are my observations in case anyone might be able to point me to the fix.
1. The PTO appears to work fine because I can use it to operate the R-4C in transceive mode using the xmtr PTO. There is no transmit power
2. The sidetone works well and the radio keys.
3. The RF Tune will peak as it should.
4. There is no dip when tuning the plate. In fact there is a peak oddly enough.
5. Adjusting the Load control has no effect on plate current. Relative output is unchanged when adjusting the plate control.
6. These measurements were made loaded into a 50 ohm dummy load.

Hope I am lucky and it is only a tube. However I am seldom lucky; thus, I sent this email. Thanks to all who respond.
George K4GM

George -

If you set the T-4XC for 80M and tune the RF TUNE down around 6.5 on the 0-10 scale do you get any plate current in TUNE??

Since you say it controls the receiver ok in TRANSCEIVE, that means that the BAND oscillator and PTO and PreMixer stages are working ok.

4888. FS: Drake receiver $145.00

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-06 03:05:49 UTC
From: Bry Carling
Topic: 4888 Message: 4888

FOR SALE: R.L. Drake Company Model 1280 / PRN-1000 Shortwave
Receiver

Desktop shortwave receiver. Excellent working condition. Looks like new.
Covers 100 kHz to 30.000 MHz continuous.
Sensitivity < 2.0 uV for 10 dB S+N/N. Has readout to nearest 1 kHz.
Selectivity
5.5kHz at -6 dB and 12 kHz at -60 dB. First i.f. 45 MHz, and second i.f. 455
kHz.
Tuning steps are: fast 5kHz, slow, 1 kHz. Audio output 700 mW. Has
headphone jack.
Powered from 12V or use the supplied Wall wart for 120V AC operation
(included.)

Synthesized, Microprocessor Controlled Tuning For Enhanced Reception.
Easy Tuning With Tuning Dial, Up/Down Buttons, Or Direct Frequency Entry
Via Keypad.
Bright LED Display Indicates Frequency. This large green digital display is
easy to read in any lighting situation. Receiver a built-in speaker, front-firing.
Has signal strength indicator and RF gain control switch.

Weight 4.7 lbs. Dimensions: 10-7/8" W x 4-3/8" H x 7-5/8" D

This is a USA MADE, General Coverage receiver also known as model
1280.
MINT condition. Great little Drake receiver... Similar to the Drake SW1
receiver.

Available for $145.00 plus shipping

Picture and details here:

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

4894. Another TR7 implosion cured

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-06 22:56:52 UTC
From: Craig Roberts
Topic: 4837 Message: 4894

Jim -- you were absolutely correct.

Q307 and R363 on the Transmitter Exciter Board were fried -- literally - thus killing the T/R switching. It appears as if the 220 uf electrolytic on the Power Supply Board failed, sending unpleasantness down the +10V line. Replacing the three components mentioned has restored the radio to normal operation (at least for the time being).

Thanks very much!

73,
Craig

I'm glad that you got it going, Craig!

I'll say it again, for anyone within reading distance, replace that 220 uF cap as preventative maintenance! That is probably the one cap in the radio that is under the most stress, strange and bad things can happen when it fails (or even begins to fail). These caps are 30 years old now, it's time.

I haven't noticed any trouble with any but that 220 uF on the PS board. I'm a proponent of "if it ain't broke, don't fix it". It would still be an interesting experiment, though, to document the results of cap changes. If I were going to go to the trouble, I would use high quality parts rated for 105C temperature. Not that it ever gets that hot inside the TR-7, but 105C caps are built better and generally last longer than 85C caps.

4902. Another TR7 implosion returns!

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-08 19:19:36 UTC
From: Craig Roberts
Topic: 4837 Message: 4902

Shucks! I thought I had it.

After replacing the 220 uf electrolytic on the power supply board and a fried switching transistor and associated components on the Transmit Exciter board late yesterday, all seemed well. Receive and transmit were normal in all modes and a simple tweaking of the carrier null and power supply board voltage put everything in order quickly. The radio acted just fine for a couple of hours.

Then -- after several faultless CW QSOs on 40 meters, I switched modes to SSB. The radio wouldn't transmit (even though SSB had worked fine earlier in the evening). On receive, the display jumped to the dreaded 17.000 MHz range, squirreled around a bit and finally settled on 17.650 or so with the receiver dead. Keying the radio on CW returned it to normal transmit operation in the 7 MHz band in that mode, but releasing the key continued to result in an incorrect, out-of-band display and a dead receiver.

Apparently, the T/R transistors(s) on the transmit exciter board are gone again -- but freezing the rig in the transmit mode this time.

I am completely at a loss here. I fear it's time to break out the bubble wrap (again).

4903. Re: [DrakeRadio] Another TR7 implosion returns!

Craig -

The 17 MHz output just means the low band PLL is unlocked.

When you were working on the radio did you happen to measure the +24V bus? Unlocked PLLs that 'sometimes' lock are often an indication of low +24 V. If you switch to 20M or above does the frequency lock, or does it wander up to about 32 MHz?

The transistor 'fuses' on the Transmit Exciter board are just that. Totally unprotected and even a momentary short or overload on the 10R or 10T bus will kill one.

Yup -- it does wander up to 32 MHz or thereabouts on the higher bands.

Convinced my problem stemmed from the 220 uf electrolytic and the 10 V
line alone, I did NOT check the 24 volt line (foolish me). It could be,
I suppose, that another problem has befallen the power supply board.

I'll let you know.

Thanks very much, Garey.

4905. Hello, and a question

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-09 23:34:31 UTC
From: Fraser
Topic: 4905 Message: 4905

Quick introduction, my name is Fraser, W3UTD and I just acquired a TR-3. I wanted something as a project, with no solid state devices. The rig is in quite good shape, some corrosion on the copper chassis, but at least everything is there.

I've been through it, finding and listing capacitors and resistors for replacement, but I'm having trouble finding on the schematic what appears to be three carbon comp resistors paralleled around a wire wound, not factory I would suspect. It measures 1.2 Ohms and is situated at the rear of the chassis, underneath and near the power plug.

One lead goes up top and comes out underneath the relay somewhere. The other lead goes to a feed through to another section and a small coil.

I have some pictures loaded in the photo section, look for W3UTD.

The closest thing I can see on the schematic is R45 .8 Ohm 2W, but it appears to be either side of M1, isn't that a meter?

Thanks for any help. Fraser, W3UTD

4906. Re: [DrakeRadio] Hello, and a question

Fraser -

That is almost certainly R45, which should be 1.5 ohms and is the meter shunt for metering plate current. The original circuit is R45 is 1.5 ohms, and R131 is a series resistor to the meter that was selected at test to correct the meter reading at 0.1 A. Best to replace R45 with a 1.5 ohm, 1W ceramic composition resistor, then select R131 to set the meter reading correctly. Easiest is to measure R45, calculate the voltage for 0.1A, and then select R131 to make the meter read 0.1A with the transceiver sitting upright. This is the only critical meter reading. If you are using an AC-3, there is a test point to accurately measure idle current on top of the chassis, but nothing similar in the AC-4.

Fraser -

Yeah, apparently neither one still stocks the Ohmite OX / OY ceramic comps in values that low any more.

Digikey does have the metal oxide type, which is ok, mainly you want something that can withstand current surges as it will see up to 500 mA peaks when tuning. Metal film just do not like that! :-)

The Yageo RSF200JB-1R5 should do fine.

R131 can be anything from about 50 ohms to 270 ohms 1/2W depending upon tolerance of R45. Probably a lot narrower range now with better shunt resistor accuracy! :-) While you're ordering, you might want to check and/or replace R119, 120 and 121, along with R42, 43 and 44. These affect the balance of the three output tubes and you want to keep them as close as possible to evenly share the total current. Metal oxides are good there too, as they are non-inductive and able to handle current.

What's wrong with wire-wound resistors for this? They
can stand enormous short time overload and tend to be
stable.

Garey, thanks for the help. I have a question though. I can't find R131.

I have been over the schematic that is in the manual that came with the rig until I had a headache, but I couldn't find it. I then went online to the BAMA archive and looked at one, and I think I see R131 right next to one side of M1, but it is a very fuzzy image.

It's definitely not in my schematic, and it's not in my rig. The S/N is 1255. Would that put it as a low number, and possibly R131 was a later mod?

Fraser

I'm having trouble finding on the schematic what appears to be three carbon comp resistors
paralleled around a wire wound, not factory I would suspect. It measures 1.2 Ohms and is
situated at the rear of the chassis, underneath and near the power plug.

Probably nothing wrong with wirewound for R45, a little more expensive, but not significant. I'd be reluctant to use them in the other places though. I've been working with RF long enough to avoid connecting anything with inductance, no matter how small, to the active elements of high gain tubes. Ya just never know, I've seen some hard to locate problems.

Fraser -

Look at the schematic near the bottom and look for 7-10 digit number, probably ending in 0001. This is the schematic s/n, in ddmmyyxxxx form. Some used single digit days and months. The only two schematics I've ever been able to find are 1018633001 and 6186410000, so if yours is a different number or no number I'd love to get a clean copy of it.

Yes, it's likely that R131 was an addition. It is located just above the shunt resistor and meter, and obviously is just jammed in there on the schematic. The 3001 schematic shows the last resistor as R132. The designer probably thought a 5% resistor was close enough since the AC-3 had a test point for setting idle current. This current is pretty critical for distortion and tube life and needs to be set accurately. The shunt resistor/selected series calibration resistor is used in all the 4 Series transmitters as well. The meters used were NOT precision units, and cost less than $1 at the time. Again, all that was critical was the idle current setting, so if they were 'calibrated' to read correctly there, the rest really didn't matter!

The number is 6363500 and it also says "Highest resistor is R118", so no wonder I can't find R131.

I'll see what quality of copy I can scan ...

Fraser -

OK!! That's probably the first one. If you can make clean scans at 300 dpi or better of left, right and center, I can put them together. I'd really appreciate it!

I wonder where the other 13 resistors were added?!?! :-)

I will have to see if I can find a WW of about this
value to test. I have a Boonton RX meter which was intended
for just this sort of thing. It goes up to about 250 mhz and
will indicate the series reactance of components. Its
capacitive range is pretty limited but it will measure
reasonably large inductances and can find resonant frequency
although thats a PITA requiring several measurements
bracketed in frequency.

From: Bry Carling
Topic: 4916 Message: 4916

DOLLAR TUBES:

Pair of Planar Tubes - one is an Eimac 2C39 - the other looks the same but has a larger heatsink on top. Probably another brand of 2C39.
Will sell the pair for $2.00

2E26 tubes - good used. Will sell two for $2.00

Others: Cunningham 327 (looks new) - $1.00

RCA 6X5 - $1.00

Group of 5 tubes including a 2C51, 5670, 6C4, 6AL5 and a little triode (6C4?) - all 5 for $5.00

Philco 5V4 - $1.00

RCA 5Y3 - $1.00

OB2 regulator Sylvania - $1.00

6BM8 - ECL82 - Britain - $1.00

All of the above for $13.00 plus shipping

73 - Brian, AF4K

Hello to the Group ,

i am looking for a MC14558 IC (Ref Number 9029 at the DR-7 Board) DRAKE No. 3041138.

Its a BCD to 7 Segment decoder.

I need two of them , one for the board and one in stock.

In Germany i found no distributor for this IC.

Maybe its possible to use a simular type ????

All answers and suggestions and idears are welcome.

Regards from Germany

Joachim

4922. 34-PNB Noise Blanker alternative?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-14 15:56:10 UTC
From: billykatzz
Topic: 4922 Message: 4922

I'm running a TR-4Cw and am very happy with its performance. However, I'm curious to know if the noise blanker addition makes a big difference in the receiver's performance or not (the knob on the lower right-hand corner of the panel has always intrigued me)

Currently there's a 34-PNB offered on Ebay for the "buy it now" price of $299, which is almost as much as I paid for the transceiver. Are there any less expensive ways of either homebrewing or modifying a noise blanker for the TR-4's?

Bill in Pasadena

From: Craig Roberts
Topic: 4919 Message: 4923

So...

To make a long story short (so to speak), it would now appear that the T/R switching transistor(s) on the Transmit Exciter board in my TR7 are blowing when I change modes. It seems this would be caused by a transient or short on the +10V line when the mode switch is exercised.

This has occurred three times. The latest symptom: The receiver goes dead with the display futzing around in the 17 MHz region (changing to 33 MHz above 20 meters). When the rig is keyed on CW, transmit is normal. This has happened twice. The first time this failure occurred, it was the transmitter that died and Q307 literally exploded.

Where in the heck is this coming from? The power supply board is fine. I have two of them -- both with replaced 220 uf electrolytics -- and the failure is common with either one.

Bill,
That "high price" is what has kept me from pursuing noise blankers in any of my Drake rigs. I did get lucky with the noise blanker being in one of my R4C's, BUT the Drake noise blankers only work on short duration noise like ignitions and electric fences. It does little or nothing for atmospheric noise. I haven't found any "after market" noise blankers for sale, but hopefully someone will design one eventually. "Cracker Box" welders and electric fences are my only plague out here in the woods, hi.
73,
Don, WB5HAK

Wellllll. Since it was at least working on transmit, perhaps the problem is on the 10R bus. Assuming a 'mechanical' inspection shows no shorted or broken wires, next most likely is a failed electrolytic cap. One approach is to just apply +10V to the 10R bus and see what pops! :-)

A more scientific, (albeit less exciting,) method is to make up a 'truth table' to see what happens when.

At turn on, the VCO is unlocked. Is the receiver working?? An unlocked VCO is just a moving LO, so if an antenna is connected you should hear signals (or a generator) as it sweeps by. The 24VDC supply is involved in the 'steering' of the VCO, to preset it to where the PLL can capture it. Does it continue to work, just settled around 17 MHz? No blown Transmit Exciter 'fuses'?

When you switch modes, does it matter 'which way' you are switching? Particular modes?

If you key the transmitter, the out-of-lock should keep it from transmitting. Does the 10R fuse blow when you switch? If not, does it blow when you return to receive? Does the 10T fuse blow? When? Do they BOTH blow???

With the TR-7, if cleaning the card and cable connectors doesn't fix it, the next most likely fault is one of the MANY electrolytic caps. The dipped tantalum caps seem to be much more reliable, but the aluminum electrolytics are failure prone.

Thanks, Garey. The 'truth table' approach certainly makes sense although applying 10 volts to the 10 R line does, indeed, sound exciting. I am intrigued by the simple efficacy of the 'flames n' smoke' troubleshooting method (which I have employed for decades).

I think -- and I emphasize 'I think' -- the failure occurs when I switch out of CW mode and back into it.

I am wondering of the problem component resides on the PBT board.

The last two statements do not necessarily relate to one another.

Craig -

Which 'fuse' blows? Both? In what order?

Do you have an extender board set?

4928. Re: [DrakeRadio] 34-PNB Noise Blanker alternative?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-14 20:11:03 UTC
From: Paul Pollock
Topic: 4922 Message: 4928

Hi Bill NK6Q,

The Noise Blanker came with my TR-4, and I would never own a radio without it. In my locality, I presently have a constant S-5 noise level (AC line noise, I have a 203R power transformer within 60-ft of my antenna), and the Drake PNB-9? brings that down to a S-2/3 routinely. This boils down to a increase of 12-18db more receiver gain at the noise-floor end. On my old antenna, I was getting a noise factor of S-9, and the Drake Noise Blanker could still pull that down to a S-2/3. When you find one, be sure to align it. They get out of calibration over long periods of time.

I am a relative newcomer to Drake products, but I will tell you that a working Noise Blanker has no business quieting atmospheric or generalized noises. It is only intended for spikes. However, the Drake adaptive Noise Blanker scheme does work effectively on many more types of noises than the inventor of the circuit ever intended <grin>.

There is a good article on the "HFN" website about using the Noise Blanker out of a TenTec-555 transceiver, however it cannot be used in a Drake transceiver as it is mono-directional (works in the TenTec) and the Drake transceivers require a Noise Blanker that can handle signals in both receive and transmit. But it may give you a direction to start with. Otherwise, I would wait for a cheaper PNB-34, as $300 is way to much for a board that was included in virtually all TR-4C models, as I recall reading. And in earlier radios was a sub-$50 option; even accounting for inflation, this board should be less than $100.

Anyone who takes the PNB-34 out of an existing transceiver is in my book a slug beneath contempt. Why doesn't the likes of that kind of EBay'r take out the transmitter tubes and sell those separately while he's at it, or sell the sheet metal separately. Sheesh, sorry to vent, but I see this kind of junk on EBay far too often. Only good excuse for seeing a loose PNB-34 is when a radio becomes not-economic to repair, and the only thing that can be stripped for parts is the Noise Blanker board.

Same thing happens on EBay where one might be shopping for a good laptop; quite often the hard drive or the power supply brick is not included. These both came with the machine, and parting it to boost the overall price is contemptible. Even the argument that the seller says he's protecting the next owner from his data security, is baloney. There's all kinds of software that can effectively wipe a drive to the extent that DOD can't get anything from it, is cheap or free. Macs can do it from inside the OS. Any seller that needs to take security precautions by removing the drive, is ignorant, in the extreme, or a damn liar. There's no third way.

Again, I apologize if I've gotten too windy. Have fun with your search, and good luck!

The first time this happened, Q307 burned up (literally), disabling the transmitter. In two subsequent cases, Q308 has gone, killing the receiver. Sadly, I do not not have an extender board set. Guess I could use one, eh?

Craig -

Q307 and Q308 are both on the 10R receiver bus. Q307 IS the fuse, but Q308 is the control and shouldn't be damaged unless Q307 is shorted. Are you sure you got the replacement in the right orientation?? Both are E-B-C, leads toward you and flat up. Q307 is PNP and Q308 is NPN.

The most important part of the extender set is the Jumper Board that bridges two boards and allows the radio to run without the DR-7. You DON'T want to be removing and replacing the DR-7. Best extender option is Bob, W7AVK <http://www.wb4hfn.com/Services/W7AVK/tr7ext2.htm>.

Important note: the Drake authorized general coverage transmit mod disables the out-of-lock transmit inhibit. It WILL transmit unlocked! This is why I came up with a better mod that does not disable the OOL inhibit.

Jerry,
I don't know what a dip package is? 14 dip?
Does it come some other way?

I remember it is like a 14 pin dip chip?

I don't do much with solid state.
Mostly old tube stuff.

Some day I might get back into the low power building. HI HI

Thanks,
Teran KF0HR in North Dakota

Bill,
First, whether you need one or not depends on your environment. The Drake noise blankers all worked very well on removing pulse type emissions. This is not to be confused with the dsp noise reduction of today's new rigs. We could get technical, but sometimes is just best to pass along experiences. I once owned a R4C and all the options were installed, including the noise blanker. I recollect trying to use it several times, for power line noise, but it made no difference. Once there was some work being done nearby and I was picking up some engine noise from a large machine. The NB took it right out.

My current TR4C does not have the noise blanker, and I have not found an occasion that made me wish it had it inside. I continue to marvel at the receive audio and sensitivity of this radio, when compared to my new Ten Tec, Icom and my TR7. I've used the TR7 over the last 10 years quite a bit. Its got the NB7 installed. I think I've used it one time where it actually eliminated some noise,...again it was a pulse type noise.

I'd suggest to you that its not worth an additional $300 to have one. I've often wondered why someone has not offered a board or kit. I've heard its due to obsolete components. However a redesign would be acceptable if it worked, ... and at the same time, it might be improved upon. I seem to recall some efforts by a German ham in making a board for a TR7, but not sure. In summary, you should just have fun with the rig and put that knob out of your mind !! Hi Hi.

Hello to the Group ,

i am looking for a MC14558 IC (Ref Number 9029 at the DR-7 Board) DRAKE No. 3041138.

Its a BCD to 7 Segment decoder.

I found a Distributor , but he can deliver only the MC14588BCD IC.

can i use this IC for the original one installed on the board ????.

All answers and suggestions and idears are welcome.

Regards from Germany

Joachim

Hallo Joachim,

Try this site

http://www.elettronicashop.it/ITAITA65N126-mc14558-circuito-integrato.htm

They apparently have the IC in stock, at 1,20 Euro each, with VAT.

I have no experience in trading with them, so I can not comment on their
reliability as suppliers.

But you may want to check them out...Let us know the results, OK?

Kind regards,

Jorge

Grant -

No real 'adapter' needed. A piece of coax, RG-58 / 59, or low capacity microphone cable, as short as possible. The receiver end center conductor goes into any of the ACCESSORY XTAL sockets on the back panel. It needs to go into the pins that are all tied together with a piece of bus wire. Then the shield needs to go to chassis ground nearby, NOT the 'other' crystal pin. Then switch to ANY crystal switch except for NORM. The cable should be disconnected at the receiver end when crystals are being used, although there is no longer any reason to use crystals!

By the way, the FS-4 will be 10 kHz off frequency for ONE of the two receivers. The "B" and other 4 Series Ham receivers need an injection frequency that is 11.1 MHz above the bottom end of the desired band, while the SPR-4 requires 11.09 MHz. The crystal in the FS-4 must be changed to the 'correct' one for an accurate dial reading, i.e., 9.6 MHz for the R-4 series, and 9.59 for the SPR-4.

4945. Drake MN-2000 vs MN-4

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-16 21:16:39 UTC
From: billykatzz
Topic: 4945 Message: 4945

Another question to the Drake gurus out there:

With the thought that I might want to go QRO sometime in the future, I recently picked up a Drake MN-2000 matching network. Currently I am using an MN-4 with my TR-4Cw running barefoot.

A few months ago I strung up a G5RV antenna in the hopes that with it and the MN-4 I might be able to work 80 meters. Unfortunately the MN-4 doesn't seem to be able to get a good match on 80 with the antenna.

I understand the MN-4 is somewhat limited in matching, so my question is: does the MN-2000 have a greater capacity of matching than the MN-4, or is it pretty much the same performance with the exception of being able to handle higher power output?

Bill in Pasadena

Off hand without knowing the particulars I would say that the antenna was at fault or the feedline. My TR-4C does just fine with just about anything I hang on it. For barefoot use I would take the MN-4 out of the loop. The tune and load control on the TR-4 will do just as good without the loss from the tuner. What version of G5RV are you using? Is it cut for 75-80 mtrs? More info from you will return more info from the group.

Hi;
I am new to the group and I just got a real nice Drake TR-4, I checked with the previous owner, he told me the it put out about 150 watts and he only ran it at about 110 to 120 watts, but knowing that if I tuned it up to max watts out, I was wondering if the 902 could handle the load. I just wanted some real life experience from any member that used or uses a tuner say less than 300 watts.
Thank you
Wayne

I have used that little tuner and it worked just fine---after soldering
about 5 never soldered correct connections in it. That done it was FB at
couple hundred watts. It is rated at 300w pep I recall.

Hi Paul:
Thank you Paul for the info, I kind of suspected that it would be able to handle a full load, as the tuner has, it seems, beefier components in it, I will give it a try and see what happens.
Thank you again for the info.
Wayne

Denny:

I understand that the older tube transceivers can handle high SWR better than more modern rigs, but wouldn't trying to load the TR-4 directly into "just about anything (you) hang on it" potentially damage the rig, particularly the finals?

My G5RV is a homebrew 102 ft. dipole with 34 feet of homebrew ladderline going to a 1:1 toroid balun. Part of my problem may be that a portion of the ladderline is resting on my asphalt-shingled rooftop.

Although I can't get the MN-4 to tune to 1:1 SWR on 80, on 40 and 20 it's no sweat and the performance seems to be really good. This morning on 40 I worked Japan, Korea, Guadalajara, the Bahamas, and Sakalin Island. For running barefoot with a compromised G5RV I can't complain.

Hello Bill. The older tube transmitters can handle the higher swr due to the fact that the output network actually adjusts to the antenna load hence the LOAD capacitor. It is a sort of tuner in itself. Adding the outboard tuner can cause problems by adding loss and mis-matching can occur because you have to tune the rig to the tuner and then tune the tuner to the antenna. Just one more thing to cause problems. If you were using a solid state finaled rig the transistors in the final cannot stand a mismatch and have no built in tuning network just a system to reduce current to a level well below the operating specifications of the device to "save" it from destruction. The tubes when properly loaded may see some small variation in swr but can handle that. Swr changes can occur from rain, snow, humidity, leaves and even atmospheric conditions.

When you tune the load control on a tube rig you can tell if the SWR is high (or low) by reaction of the final tune adjustment (plate). In most cases it will not have any real effect on the signal. If the load (antenna) is open or shorted it will not load. Just take it back to standby or receive and go investigate the problem.

As for your custom hand made ladder line, are you running it directly to the tuner? Or is it through a balun or matching section? And I guarantee that it laying on the roof is having adverse effect. Even being in close proximity can cause strange weirdness. It needs to be 90 degrees from the feet point. Just one of several problems encountered with ladder line.

And finally have you done any trimming on the antenna length? The G5RV has inherent problems with 80 and 10 meters. Possibly removing an inch or more will bring it up in frequency. Here is some good info on the G5RV from G3TXQ:

http://www.karinya.net/g3txq/g5rv/

Personally I prefer the off center fed dipole.

Good luck
73
Denny

Denny:

Thanks for the info. I'm certain you're right about the ladderline lying on the roof: I'm addressing that by making 8 inch spacers out of cheap plastic planter pots I picked up at Orchard Supply (they're also black, which is the same color as my roof shingles, so they should not look too obtrusive)

I initially tried just running the ladderline down to a 1:1 balun and then to a short run of RG213 into the shack, but everything went haywire. Things got better when I cut down the ladderline to the requesite "magical" 34 foot length. So the ladderline now terminates in the 1:1 toroid balun (from Balun Designs) and an extension of RG213 takes it down to the entry point of the shack.

The ladderline is definitely 90 degrees coming off the antenna (sure looks "purty" too hanging down above the roof), but I haven't attempted trimming the antenna length. I want to get to the low end of the band for CW only, so wouldn't I actually need a slightly longer length G5RV, or are we inching towards a regular 80 meter dipole?

Bill the antenna you have is not a true dipole as the feedline is also radiating. Maybe you could beg, borrow or swipe (just kidding) an antenna analyzer and run through the bands and actually see where you are resonant. Could be a big surprize. Maybe some of the other guru's in the group have some experience with similar circumstances. But play away as it is all part of the experience of antenna farming. Wish there were "magic seeds" for antennas. Other things that will influence the antenna are ground conductivity (soil makeup) and other trees, poles, utility lines, fences and buildings. Also your station and building grounding. So many variables. It could drive a crazy man sane. Good luck

Hi Dennis,

Pardon me, but you might consider this line of thought which I've followed for years, even unto today -

Tune the Drakes into a 50 ohm dummy load DIRECTLY, without the "tuner."

Then, without touching Plate - Load on the Drake, key up again into the "tuner" and tune the external MN-4 or whatever to "match" the antenna for lowest SWR.

Works for me without fail.

If the load (antenna) is open or shorted it will not load. Just take it back to standby or receive and go investigate the problem.

As for your custom hand made ladder line, are you running it directly to the tuner? Or is it through a balun or matching section? And I guarantee that it laying on the roof is having adverse effect. Even being in close proximity can cause strange weirdness. It needs to be 90 degrees from the feet point. Just one of several problems encountered with ladder line.

And finally have you done any trimming on the antenna length? The G5RV has inherent problems with 80 and 10 meters. Possibly removing an inch or more will bring it up in frequency. Here is some good info on the G5RV from G3TXQ:

http://www.karinya.net/g3txq/g5rv/

Personally I prefer the off center fed dipole.

Good luck

Excellent advice, Howard!!! FYI, if you don't follow Howard's advice, you will end up chasing your tail on most antennas until you have NO 6JB6's left!!! The only thing I might add to Howard's procedure is after you have reached that "lowest SWR", that you peak plate one last time to insure you have the "dip" in the best place for the plates.

Thanks, guys.

Actually, that's my procedure too. I'll tune the transceiver into a dummy load and then switch to the antenna. I lower the transmitter gain control and tune the MN-4 for lowest SWR, then turn the gain back up: good to go.

I hadn't heard about retuning the plate control for optimum dip afterwards, but that sounds like a good idea. Of course, if the dummy load is presenting a 50 ohm load and the MN-4 has been tuned to match, ideally they should be the same.

If you are tuning a tube type transmitter with a Pi Network output in to anything less than probably 100 ohms you really do not need a tuner.

A tuner does not fix antenna problems. It only hides them from the transmitter. Tuners did not become commonplace until the switch to broadband solid state finals.

Heath did not sell the SA-2040 and SA-2060 until they were selling the SB-104. It needed a tuner. The previous SB line did not need a tuner. The Pi Network is the tuner.

Same here, with my amp. I tune up (L-7 in CW mode) into my turbo-DL-1000, then switch the MN-2700 to the matched antenna.

Before anyone asks, the turbo-DL-1000 is a 32 CFM fan on a standard DL-1000. Pulling air OUT.... :)

I usually tune into a dummy load if moving the transmitt frequency very far. Then the tuner gets adjusted to the antenna with about 25 to 50 watts. Then back to the rig or amp for a full power tune up going into the tuner.

The rig or amp should be the last thing to be tuned as your dummy load may not be exectally 50 ohms and the input to the amp or tuner will not be exectally 50 ohms.

If the swr is less than about 2 or 2.5 to 1 then the tuner is not used. For solid state rigs without a built in tuner I usually go through one if the swr is above about 1.5:1 or where the rig cuts back the power.

4962. are there differences between the B-line and C-line PTO's?

I have not received a response regarding my quest to find a C-line PTO, but I have found one from a T4XB. obviously the dial mechanism is different, but I am wondering if there are any changes that would prevent me from replacing the old dial/gear mechanism with one from my R4C. the feel of the tuning dial on the R4C is silky smooth and I would love to have that on the replacement PTO. it has the metal gears and is perfect. it's conceivable that the tuning ratio was slightly different, necessitating a different winding on the inductor. I doubt this, but I've found it best to ask questions before purchasing!

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

Daniel -

I don't 'know', but the frequency range covered is identical. It's possible that you could just remove the PC board and change it to the other one, BUT the cores were not perfect, and I understand that the core and coil were always kept together.

Again, I've never compared them directly, but it would be interesting to know if just a board swap would retain linearity. You could always swap the boards back if it was not satisfactory.

Is there a reason you're not just repairing the C-Line PTO board??

Interesting question and let us know what you discover!! :-)

Hi Paul:
Thank you Paul for the info, I kind of suspected that it would be able to handle a full load, as the tuner has, it seems, beefier components in it, I will give it a try and see what happens.
Thank you again for the info.
Wayne

I have used that little tuner and it worked just fine---after soldering about 5 never soldered correct connections in it. That done it was FB at couple hundred watts. It is rated at 300w pep I recall.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-21 01:10:52 UTC
From: arsnf7z
Topic: 4962 Message: 4967

well Gary, it's a long and sad story. the PTO in my R4C developed a drift problem, in the radio, and on the bench, where it drifted 1.5khz over 8 hours ... slowing down but never really settling. my other PTO's settle within an hour. so, I replaced the active components without success, then sequenced through the resistors and capacitors without luck. using a lab bench supply, I supplied the 10.0v directly and all bias voltages never changed appreciably over the duration. the drift always remained the same and in the same direction (increasing). I swapped out the capacitors in the tuned circuit with the same results, which left only the inductor. in the process of swapping capacitors, I discovered how critical the tracking is, and managed to break the windings on the inductor. after my best repair, the tracking was unacceptable, and the drift still existed! drat ...

so, I took the PTO out of my T4XC and it is rock-solid. it just happens to be the one dial mechanism that has fallen out of favour. I've reworked it a bit, and it is good but not near as smooth as my metal-geared anti-backlashed PTO original to my radio (sn:27k). I now see that the entire dial mechanism has been changed so I'm not sure I can swap gears on a different tuned core. perhaps.

one final point .. always hearing intermodulation-distortion from the product detector of the R4B and R4C, I finally decided to install the Sherwood detector which cleaned it up and made listening enjoyable once again. highly recommended.

Jim -

Welcome to the group. The L-4B will be 'findable' relatively easily.
The TR-6 however is considerably more difficult a find.

There are some mixed messages regarding Tony Mills, but I have recently
heard from a very reliable source that he HAS indeed stopped
production. His website was still up the last time I looked, so I
suppose it's possible that he has a few odd panels left to dispose of.

There is a LOT of useful information stored away in those archives.
They're not easily perused, but when the search function is working you
can narrow down the amount of chaff.

Feel free to post any wants or calls for help! :-)

4970. TR-4C recap recommendations?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-22 20:56:22 UTC
From: w1kilofoxtrot
Topic: 4970 Message: 4970

I'm back on the case, getting my TR-4C up to snuff. Got nice new (to me) filters in, and the carrier oscillator crystal replaced and on frequency. I decided to put LEDs in to replace the #47 bulbs. I picked blue for the meters, red for the sideband indicators. I put a bit of shrink wrap on them, so light doesn't spill, kind of like the metal clips on the existing bulbs. I like the look, and I didn't change any of the filters, so can go back in a blink. I got the bulbs from www.cointaker.com. Fast shipping, great pricing, I highly recommend them!

I've picked up a bit of 60Hz hum, so I think I'm losing an electrolytic somewhere. Before I start digging around, is there a short form listing of all of the likely caps that should be replaced? It might save me a few precious minutes of searching :-)

And, of course, the relay contacts are now dirty, so I only get receive sometimes after I activate the relay a bit.

Never ends! Good thing I like it, or I'd be forced to get rid of it!!!

73,
Steve

Steve -

IF it's _really_ 60 hz, (not 120 Hz,) then it's either the BIAS supply in the AC-4, or possibly heater-cathode leakage in a tube.

If it's actually 120 Hz, then the 'other' AC-4 filter caps and the four section electrolytic inside the TR-4C is suspect.

Tom at 'hayseedhamfest.com' has a kit that includes the TR-4C can type electrolytic along with a couple of other small electrolytic caps for a very reasonable price. The AC-4R kit from 'heathkitshop.com' is a good way to go for the AC-4. ALL of these caps are many years past their 'expected' life. Yes, a lot of them are still working fine, but any one or more could fail tomorrow with catastrophic damage, even if the TR-4C is just sitting in RECEIVE. The odds of a failure are considerably higher this year than whey were ten years ago. The odds are also higher tomorrow than today!

Hi Steve W1KF,

I had most of the same problems as you, when I got into a Drake TR-4/AC-4 package, about a year ago. First thing I did was to get the AC-4R kit and install it (killed all the humming I was getting on the radio).

Then I sent the radio to Jeff Covelli (a very reputable Drake Technician) and let him refurbish the radio. I was very lucky, the radio needed no parts, just an alignment, and some cleaning. He also tried to fix a sticky K2 relay drive circuit (which occasionally dogs me these days since. I think the relay is fine it just sticks occasionally because a circuit doesn't quite close when I want to tune-up). Jeff sent it back looking and working almost like new, and works like it should. It is still putting out 200-watts on 80-meters with the tubes that came in it, and hears a rats' whisker <grin>. Best sounding radio I have ever used in 40 years of radio, should have done this a long time ago.

I originally bought it to have a tube radio in case we get Sun-Flared severely, and my solid-state radio fails. TR-4 now on a shelf in storage, for now.

This group is a great resource for new Drake owners like you and I. There are quite a few helpful folks that enjoy pitching in, to keep those old radios still glowing <grin>!

Have fun and good luck!

Hi All:
I have recently joined the Drake radio Users' group earlier this month, my name is Wayne and have been a ham since 1974 and currently hold an advanced ticket.
I recently purchased a very clean TR-4 with the MS-4 and AC-4 power supply and D104 silver eagle desk mike, and am very happy with it, and it works great so far. The previous owner had the radio aligned and the power supply rebuilt in 2008 by a well known Drake radio technician.
I really do enjoy the group with all the very informative information that is shared it really makes for some very interesting reading.
I just wanted to introduce myself to the group, and tell you guys/gals thank you for letting me be a part of this great Drake family.

Paul,

This is not my first trip to the bench. I had a pair of TR-3s a couple of years back, which I went through. I didn't want to sell them, but I did want to experience a 'modern' radio, so I sold them both and got an Icom IC-718. Loved it, but missed the warm glow.

So, I found this TR-4C in a little rough shape; and have been bringing it back, little by little. Learning a lot from the fine folks in this group as well. Looks like a full re-cap is in the works real soon now.

Part of the joy is doing it myself, part is that fact I just bought a Yaesu FT-950 to get a feel for DSP signal processing, and I'm loving that too. But, it's removed a large part of discretionary income that I might have had an urge to leave with Mr. Covelli (sorry, Jeff!)

The Drake will stay, the Icom, sadly, will find another home, since I don't need 3 HF rigs. It's in like new condition, with all original accessories. I just haven't gotten to doing anything about it yet.

Welcome to the group, Wayne!
You will find this a VERY helpful group as you experience problems with your Drakes. At their age, they will "hiccup" at times and cause us to scratch our heads. Many knowledgeable hams frequent this group, and help is usually right at hand. Enjoy your Drakes!!
73,
Don, WB5HAK

Good evening,I'm new to the group.
I'm looking for some optional crystals for my R-4B rx, maybe you have a few spares or unused ones?
Coverage needed is (real frequency is + 11,1)
1,5 mhz (180 m)
3,0 mhz (90 m.band)
9,5 (31 m band)
11,5 (25 .band)
13,5
15,0 (19 m.band)

PM are welcome.

Thank you
Best 73s- Giampaolo, Italy

From: Paul Pollock
Topic: 4970 Message: 4979

Hi Steve W1KF,

Oops, my apologies about you being a new guy. Fixing radios can be fun, but I had a bad scare once trying to fix a tube amp awhile back. Damn near fried me to the ground. So now I let braver individuals do it when I can <grin>.

TR-3's are nice radios, but I got spoiled by Noise Blankers, so I was glad to get a TR-4 with the Blanker. It really does help on noises in my locale.

FT-950 is said to be a very good radio. I'm using a FT-450at on my present station. Only thing about the FT-450 I don't like is it don't have an Auto-Notch, but the FT-950 is almost double the cost. So I'll stick with this for awhile.

I did look at the IC-718, several of my friends swear by them. But I've used its' DSP when I used to have a R-75 receiver (with the AM-Synch and modified to work). Great radio, but the Notch filter only works on 2.5 tones (spec from a tech I know at Icom), and there are many times when the thing has to work on more than that. I eventually sold it to one of my friends who had a IC-718, he wanted to create a set of splits (as some folks have <grin>). R-75 is a much better receiver than the receiver in the IC-718, by most accounts. He sold me the Drake TR-4. It was an excellent trade, both of us got exactly what we wanted. He has since also acquired a set of "B" series splits, and wants to put that on the air when he gets them refurbished.

When I can find one in good shape, I would like also to acquire a Drake R-4b receiver, just to see how it does against the TR-4. Articles on the web suggest it is much more sensitive, while remaining a quiet radio. Only minus in the Drake line, is that the UP-Conversion scheme does not let me use the R-4x receivers to hear signals in the Tropical Bands. Especially the frequencies in the 5.8-6.5Mhz range. I like to listen to AM Broadcasts in this range. I understand why I can't, but it's an irritation anyhow <grin>.

I hope you get the TR-4c fixed soon, I'm sure it will serve well.

Paul,
You can listen to frequencies in the 5.8 to 6.5 range with any R4(x) receiver. It's only the 5.0 to 5.5 that you shouldn't TRANSMIT in, you can listen there too as far as I know. In any case, 5.8 to 6.5 is certainly allowed. I do it all the time.
73,

Hello group. My name is Jim (WB6TNF). I am new to the group. I recently aquired a TR-4CW/RIT, MS-4, AC-4 & MN-2000 all in Mint Condition. I am still looking for a TR-6 and L-4B to round off my collection (Drake Station). Also does anyone know the status of Tony Mills the Drake Front Panel guy? I have tried to contact him with no luck so far. I am looking forward to future posts (and reading thru the archives).

The SB-200 only buys you one s-unit. (200 W output > 500 W output.)
Not to mention that you have to dump more than half of that 200W
'somewhere else' as heat.

Hi Garey!!..

Heathkit specs state the SB200 is rated at 1200w input on SSB, PEP, and 1000w on CW.....

Mine puts out close to 600w, (Average) in Tune, into a DL, 80w from exciter, according to my Bird.

Joe -

Precisely. 200 W you have now, to 600 W is 4.8 dB. One Drake S-unit is
5 dB. Plus you still gotta dump 120 W 'somewhere'.

Hardly seems worth the cost / complication ??

I have managed to enjoy a 40+ year career in amateur radio without ever owning or even operating a linear amplifier -- but I understand the psychology. After all, I own a 193hp motorcycle that tops out at 206 mph. Its capability is completely useless in everyday riding -- and beyond my "vintage" skills on the track these days -- but it sure feels good!

You are welcome, Paul. 5.8 to 6.3 would actually be the range of one crystal. If you want full coverage to 6.5, you would need two crystals and would actually get 5.5 to 6.5 but we can't transmit there anyway, and that band is fun to listen to in the evenings.

Garey:

Thanks for the info. My TR4Cw doesn't come close to 200 W output, more like 120 with fresh 6JB6's, according to the wattmeter on my MN4 tuner. However, I'm loading up the rig to a max of 350 mA on the plate current, according to an addendum in my manual.

I'm operating CW only, so what stupid thing am I doing/not doing?

4996. TR4Cw double dip on 80?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-25 16:38:48 UTC
From: billykatzz
Topic: 4996 Message: 4996

Sorry for all the dumb questions, but can't find any Elmers around Pasadena who know tube gear. How sad.

I may have finally figured out how to get my MN4 and G5RV to cooperate and let me get on 80 without a bazillion-to-one SWR. However, I'm confused about several issues:

I've found on 80 that I get a dip on the plate control at around the 9-10 O'Clock position. I found a stronger dip reading around 3 O'Clock, but the SWR on the tuner/antenna combo goes way up and seems to "like" the other dip better. What's going on here?

Also, after tuning the rig up in what I "think" is the correct method on 80 meters, according to the internal wattmeter in the MN4 I'm only getting about 80 watts output.

So what am I doing wrong?

Bill in Pasadena
NK6Q (the "N" stands for Novice)

Bill,
First question, do you have a dummy load that will work with the TR4?? If so, are you initially tuning into the dummy load? The correct way to tune especially a "wide range" antenna like the G5RV is to use the dummy load to tune up the rig, THEN adjust the MN4 to get the SWR down to a reasonable level.

What I do here is use my MFJ antenna analyzer into the tuner to get the best match I can and use that as a starting point. I write down those settings, and can put the tuner on them in a heartbeat, tune the rig to the dummy load, then switch to the tuner and be VERY close to right with less wear on the finals. I don't have an answer for the "double peak" if it is to a dummy load. If you get that to the G5RV, then that's another matter and may reflect some strange impedances in the antenna. Hope that helps and is understandable, hi.

4998. 300 watt Tuner

Yahoo group: DrakeRadio (2006 — 2011)

From: trapp7318
Topic: 4998 Message: 4998

Hi Everyone:
I am interested in getting a 300 watt tuner for my Drake TR4,I am looking at possibly a MN4 or a MFJ 945,948 or 949 in good electrical and physical condition.
I have been trying to trade or sell(In QTH.com), a small mfj mini tuner and 300 watt meter to trade or purchase a beefier tuner, and to date I have had no luck in either trading for a better tuner or selling what I have and purchasing one.
Can anyone in the group help.
Thank you
Wayne

Don:

Yes, I tune into a dummy load prior to switching to the tuner/antenna, and do notice the double dip on the dummy load, which theoretically is a "perfect" resistive load, on 80 meters.

And, yes, I also have my crib sheet with the settings written down. I've found with different weather conditions (like rain) or outdoor temperatures, and at different frequencies, of course, the settings can change.

In regard to my wattage output, I'm wondering if the MN4's wattmeter could be inaccurate?

Bill,
It soundws like you have a good proceedure down and are using it just right. Yes, the wattmeter could be inaccurate, BUT remember that the meter is reading average power, not peak on SSB. Isn't "tune" mode a bit less power than full output?? I haven't messed with my TR4 in long enough that I have forgotten, hi. However, if you are in CW with the key down, then I would expect a bit more from the TR4 than 85 watts. Remember that the specs are written usually in input values, which is what we had to deal with when these were manufactured, and actual output is much less (like 1/2) of stated ratings, but my T4X(x)'s do more like 120w PEP two tubes, so you are correct that the 85 watts you are getting is low. That could be weak finals, weak driver tube, alignment needed, etc. Garey may have more tips later in the morning.

Bill
I think you could avoid a lot of confusion if you include in your arsenal a 50 ohm dummy load.
1. Set the antenna tuner to the bypass position and tune the rig into the dummy load and leave those settings alone
2. Set the antenna tuner to be inline and tune the antenna tuner to match the antenna or load to the transmitter
3. Touch up the plate tuning on the rig if necessary but it shouldn't be required or very much unless something is really wrong like the antenna tuner won't match the load.
4. Enjoy the operating

Paul:

Already done! One of my first purchases before I tried going back on the air was a dummy load. I wouldn't think about tuning the transmitter directly into the antenna.

I've been operating the TR4Cw for about a year now and have had good reports on 40 and 20.

When I was a young ham back in the mid-60's, 80 meters had always been untouchable because A) I didn't have the yardspace to erect a full 80 meter dipole B) None of my ham friends was aware of G5RV or W3DZZ antennas C) matching tuners didn't seem that widespread back then. Consequently my current fascination with 80 meters (160 meters? Fugedaboudit!!)

Bill -

Nothing 'stupid' !! The 200 W I quoted is MAX output, which is where most people run them. The reduced plate current in that addendum was recommended after the FCC reduced the allowable levels of spurious, IMD and harmonic output some years ago. I find it interesting that whatever the problem is, the T-4X(any) transmitters with two tubes are limited to 340 mA also, which results in the same power output from two tubes as with three.! These transmitters are exempted by 'grandfathering' I believe, but certainly we don't want to put out more trash than necessary.

I can't find anyone who _KNOWS_ what the problem is/was at the higher levels, but I believe it is related primarily to IMD, so if you are going to use an amp, then this becomes just that much more of a problem. I don't think that the problem is significant on CW, but could be on SSB.

All that said, I'd bet you could run the full 200W output on CW and no-one would ever notice anything different. Certainly NOT the FCC! :-) Of course from 120 to 200W we're talking 2 dB or less than a half of an S-Unit. And with 120 to 600W we're up to 7 dB, or a little less than an S-Unit and a half!! Probably not noticeable in a typical QSO, but perhaps the difference in a DX pileup! :-)

...or maybe the SB-220...if you can find one. 1k watts. Was looking for one myself until I stumbled onto my L-4B. Between the two, I definately go with the Drake though. Street prices were close enough to not flinch at it. Might need to be patient though.

God bless

I have a TR-4, a Shure 450 mic with an XLR plug, and a Switchcraft plug to replace the XLR.

The mic has White and Green wires inside a foil shield, then Red and Black

The Switchcraft has 3 connections, Ring, Tip, Shield.

I'm guessing:
Tip to Red (for PTT)
Ring to White (for Mic)
Shield to Black and Green together (for Ground)

?

This may be of help:

http://www.shure.com/idc/groups/tech_pubs/@global_managed/documents/webcontent/us_pro_450seriesii_ug.pdf

http://www.shure.com/idc/groups/tech_pubs/@global_managed/documents/webcontent/us_pro_450seriesii_ug.pdf

Between the two, you should be able to figure out what you have. The mic will beed to be configured for high impedance for the TR-4.

Garey:

Thanks for the info. That's kind of what I thought: if I adjusted the transmitter to max output rather than maintaining it at 350 mA I'd probably see close to 200 watts out.

Maybe you can address the other thread I started earlier today regarding observing two locations of dips on the plate control setting on 80 meters. One results in a reasonably low SWR tuning when I switch to my MN4/G5RV combo; the other dip seems more pronounced, but the SWR reading is through the roof and can't be resolved with the transmatch!!

I'm new to operating the TR4 on 80 meters: according to that addendum tuneup is different on that frequency too. Is it abnormal to find two settings that result in a plate tuning dip on the unit?

regards

Got it wired, it seems to work, I'll get on the air later. I'm feeling unbalanced today anyway.

Good to know, on both counts.

It should sound very good.

Bill -

Most likely cause is that you are tuning up on a spurious signal with the 'crazy' dip. You should start with the LOAD control at "0". I don't recall, but I would expect the PLATE control to dip around 4-5 on it's scale, but that's just a guess. If the other dip is above say 5, then I'd suspect that perhaps you're tuning on the PTO signal at around 5 MHz. This would indicate an alignment problem, since the PTO signal out of the mixer shouldn't be that high. If you are going directly into the 50 ohm dummy load, it should tune ok and show power with little or no VSWR. But if you're trying to tune it into the antenna via the tuner, you may not be able to find a match.

Garey:

That's my procedure. As recommended in that addendum, for operation on 80 the LOAD control stays at "0", fully CCW (counter-clockwise), as it states.

I'm tuning into a 50 ohm dummy load, adjusting the GAIN control until I get a reading, adjusting the RF TUNE for highest reading, then adjusting the PLATE for the dip. The first dip is around 2-to-3 on the the dial, the more pronounced dip is around 7-8. But the SWR is crazy at the 7-8 position and the MN4 can't even attempt to bring it down.

I tried working 80 last night and heard arcing in the MN4 at the 80B position, switched to 80A and got a near 1:1 match. Afterwards, I worked a station and received a 599 +15 report, but it was only a couple hundred miles away. At least it's nice to know some signal is getting out.

I think I remember why I left ham radio in the first place back in '70.

5018. 30M Crystals?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-27 01:23:51 UTC
From: Bob Macklin
Topic: 5018 Message: 5018

I have a T4X. I want to get a crystal for 10MHz WWV and 30M.

The manual specifies a 20.8MHz crystal instead of a 21.1MHz like my R4A receiver.

Following the general formula it should a 21.1MHz but there are apparent problems in that region?

Can anyone enlighten me?

> Bill, NK6Q
>

YOu are probably tuning to a spur or maybe doubling in the final to get you to 40 meters. When going into a dummy load, it is 50 ohms at all frequencies so no reflected power will be seen on a swr meter. . If you tune to the second dip and then go into the antenna tuner, if set to 80 meters you will not be able to obtain a good match. If you set the tuner to 40 meters, you probably will have a good match to the antenna. This is not recommended as you may even be out of the ham band depending on the frequency you are actually putting out.

Garey:

Yep, SWR is fine, 1:1 into the dummy load on 80 meter setting.

Ralph:

Aha, you may have something there. I figured it was some sort of phenomenon curious perhaps to thermionic finals and "dipped" output.

I'm assuming the rig is probably functioning properly and I just stumbled upon a quirk of the electronics/harmonics.

If I start seeing sparks and smoke I'll post a message.

Bill, NK6Q

> YOu are probably tuning to a spur or maybe doubling in the final to get you to 40 meters. When going into a dummy load, it is 50 ohms at all frequencies so no reflected power will be seen on a swr meter. . If you tune to the second dip and then go into the antenna tuner, if set to 80 meters you will not be able to obtain a good match. If you set the tuner to 40 meters, you probably will have a good match to the antenna. This is not recommended as you may even be out of the ham band depending on the frequency you are actually putting out.

Bob - I think Drake recokoned that there was some reduction in sensitivity at that range and thus recommended the 20.8 MHz crystals.

I know guys who have used 20.6 MHz ones too.

I have both the 20.8 MHz and 21.1 MHz crystals available.

73 - Bry, AF4K

Posted by: "Bob Macklin" macklinbob@... k5myj

I have a T4X. I want to get a crystal for 10MHz WWV and 30M.

The manual specifies a 20.8MHz crystal instead of a 21.1MHz like my R4A receiver.

Following the general formula it should a 21.1MHz but there are apparent problems in that region?

Can anyone enlighten me?

Bill -

You didn't specify, but I assume you mean SWR is fine on BOTH tuning spots into the dummy load.

I suspect you are tuning up on the PTO frequency around 5 MHz when you dip the plate at that higher reading, although I would expect the Mixer tuning (RF TUNE) to be able to 'discriminate' against it. You're not retuning RF TUNE when you move to the higher dip are you? If the radio is in correct alignment, RF TUNE should peak near the center of it's range at 3.8 MHz.

That would be the T7 adjustments in the Alignment procedure, but it can be risky doing just part of the procedure. Simplest answer is just don't tune to the higher reading!!

There is a rule de thumb with transmitters, always start tuning at the maximum capacitance point and tune to the FIRST dip. Any additional dips are usually a spur or second harmonic of the desired frequency.

5026. AC4R Supply Rebuild Question

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-27 22:24:45 UTC
From: Fraser
Topic: 5026 Message: 5026

I have finished wiring the AC4R board, turned it on and at least nothing blew up. A good day so far...

I went through the power supply checklist based on a page on WB4HFN's site, and all voltages check out except, I'm confused by:

"Turn your meter to AC and put either lead in pin #6 and pin #4. You should read around 12-14 volts AC. This is the filament supply voltage."

I have 14VAC on pin #4, but nothing on Pin #6. Should I have something on Pin #6? Is it an either/or, or should the voltage be on both pins?

Fraser, W3UTD

Fraser -

Pin 4 is the 12.6 VAC filament lead, Pin 6 is chassis Ground. So you should read 12.6 VAC between 4 and 6 or between 4 and chassis, and 0 VAC between 6 and chassis.

5028. Drake DR-7 board schematic question

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-27 23:00:30 UTC
From: Hans-Joachim Empel
Topic: 5028 Message: 5028

hello to the group.

i have a small question about the DR-7 board schematic. (page 4-9)

at U9032 (ULN-2003A) Pin 8 and Pin 9 is a resistor 1kOhm connected.

at the connection point from Pin 9 and the resistor is also a arrow (shows to the top of the schematic).

i think the arrow is a indication for connecting this point to ground ore +5V DC. ????????

if anybody can give me please an explanation what this arrow means.

i am rebulding a part of the board (its damaged from the owner before).

Kind regards and many thanks for the help and explanation from Germany

Joachim

Joachim -

Looks like the person who drew the schematic left off the "+5" that is
appended to all the other upward pointing arrows!!!

U9032 is part of the Display section, so I would assume that it should
go to the +5 output of U9034.

5031. TR7 implosion follow up - more advice needed

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-02-28 17:20:29 UTC
From: Craig Roberts
Topic: 5031 Message: 5031

Having been distracted by other matters (like the acquisition of a couple of nifty Patcomm rigs) I haven't been working on my TR7 problem lately. It's back on the bench now, though.

To recap (so to speak): After switching modes on 40 meters one day and keying the transmitter, my TR7's display went haywire (cycling around 17.500 MHz or so and at about 33.000MHz on higher bands). The receiver worked normally. Moments later, however, I noted a burning smell and shut down the radio immediately. The bad odor was traced to Q307 on the Transmit Exciter board. I replaced the charred transistor (which had actually damaged the circuit board beneath it) and also replaced the suspected cause of the problem, C2108 -- the 220 uF electrolytic on the Power Supply board.

After reassembly, the radio worked fine and voltages looked good for several hours of operation. Then, a variant of the problem occurred. This time, on receive (after the mode switch was rotated for the 10th time or so) the T/R replay tripped spontaneously, the display went screwy again and the receiver went dead. The transmitter worked okay, however.

I have rebuilt the Transmit Exciter board again, but am afraid to power up the radio. Obviously, C2108 on the 10 volt line was not the problem.

Now I am wondering if C9 -- the 470 uF 'lytic on the Parent Board, might be the culprit. It's on the +10V line and is wired to the mode switch, the cycling of which appears to trigger the failure. Has anyone experienced the failure - leakage or shorting -- of this capacitor? What would be the effect(s) if it did blow?

Thanks and 73,

Craig
W3CRR

Did you check the other parts in the circuit? With Q307 nuked, I would have
been real suspicious of Q308 also. It's possible that Q306 could have been
damaged during the original event too. C324 might be worth looking at.

>Now I am wondering if C9 -- the 470 uF 'lytic on the Parent Board, might

I wouldn't think so, but given it's age, it wouldn't hurt to replace it anyway.

Thanks, Jim. I already have replaced all three transistors and will renew the electrolytic, too. Good point.

I am still trying to figure out what caused the original incident, however. I figure I'll just blow the transmit exciter board again if I can't work that out. The power supply board seems fine (besides, I cheated and swapped it our with a known good one).

Hi all,
when the receiver (a Drake R-4B) is on, etx mute,NB or Cal, the S-meter dial start from S4 reading.
Same if I switch off the agc, and with the right side S-meter calibration at zero and the preselector away from the tuning range.
When off it turn back to zero, as it should be.
Any idea? I suspect that I will have to replace one or more bulbs..
Thank you and best 73s!
Giampaolo

Good morning mr.Allen
sorry for the basic english.
Just wanted to say that in my rx S-meter starts with signal 4-5 units. Overall signals do not appear to be "the signal+5" btw.
And 5 it's not my noise background, 4-5 is what I have with the AVC off. Thank you.

Giampaolo -

If the S-Meter is set to ZERO with the side mounted ZERO control, it should stay there if the receiver is turned off for a while and then turned back on. If a strong signal is heard, moving the needle up scale, when the signal is removed the meter should return to ZERO.

Do you perhaps mean that if the meter is set to ZERO, and then signals move it upscale, that it does not fall back to ZERO when the signal is removed? Does it fall to exactly the same spot on the scale? Possibly a mechanical fault in the meter causing it to stick at a point.

The meter should be ZERO with the AVC off. The meter should be zero'ed with the side control, AVC on FAST. Switching from OFF to FAST to SLOW should not cause the meter to move from zero. Turning the side ZERO control full ON should cause the meter to read up to S6 or higher.

Turning the RF GAIN control full OFF (CCW) should cause the meter to go to full scale.

Yes

> Turning the RF GAIN control full OFF (CCW) should cause the meter to go
> to full scale.

Yes, full scale. BUT back to zero ONLY when the rx is switched off.

I get S 9+5 when using the Calibrator.

Best 73s
G.

5040. Mystery TR7 tantalums

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-01 17:46:10 UTC
From: Craig Roberts
Topic: 5040 Message: 5040

The TR7 has two tantalums close together near the rear of the Parent Board. I don't have the rig nearby, so I can't tell you upon what traces they are soldered and I can't find any mention of them in the service manual. What is their value and what in the heck do they do? There are scorch marks on the underside of the radio's bottom plate at their location so at least one of the caps blew and was replaced at some time.

I am still trying to figure out why my Transmit Exciter board keeps losing T/R switching transistors. It's getting mighty frustrating.

Thanks, gurus.

Craig -

Those are 10 uF, 35 V tantalum caps, one on the +10 V (Pin 13) bus and one on the +5 V (Pin 12) bus to Ground on Pin 11 on Board 11, the 2nd IF/AF board. I don't think either one is on the schematic, probably 'field changes' to reduce BFO leakage and ...

Aha! Thanks, Garey. I'll have to look at the radio when I get home, but I think the one on the 10V line is the replacement from a failure before my time.

Hmmm.

My R-4 started doing this last night. I only have about 20' of wire strung around the "shack" for an antenna, and was just listening to 40 CW in the background when it sounded like a pretty strong signal was tuning up zero beat. After a few minutes I walked over to tune off that frequency, noting that the signal was about an S6 or so (which is a decent signal with this antenna), and when I turned the PTO knob, the "signal" didn't go away. I just turned the RX off, guessing it was probably something to do with the AGC circuit...I won't have any time to dig through the radio for a while unfortunately.

5045. R-4A prescaler mechanics

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-02 00:35:49 UTC
From: William Houghton
Topic: 5045 Message: 5045

Garey & the group,

I never quite finished the work on my R-4A and thought I might get back to it very soon. My troubles are in the area of the mechanical aspects of the prescaler. When you turn the prescaler knob the slugs of a series of transformers are raised or lowered. In my case, the movement of the slugs stop, and the prescaler knob "slips" before the pulley hits the mechanical stop. Maybe about 1/4 inch before reaching the stop. This happens on both ends of the prescaler travel. If I apply light finger pressure to the metal bar that mechanically connects all of the slugs together and turn the prescaler knob, I can get the slugs to continue their path until the mechanical stop is reached.

Q1: The slugs should move with rotation of the prescaler knob until the stop is reached, correct?
Q2: Any idea what causes the problem I am experiencing?

Thanks - Bill WA6NEQ

5048. Drake r4b VS Collins 75S Line Receivers

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-02 03:50:34 UTC
From: Russ
Topic: 5048 Message: 5048

Hi folks, I'm trying to decide whether to go with the Drake r4b or one of the 75S Line of Collins receivers. I find it difficult to justify the expense of competing with the Collins collectors and would really appreciate some advice from experienced Drake users on the R4B. Also should I be looking at the R4B or another fine Drake receiver. Looks like it's hard to beat the Drake when it comes to sensitivity from the specs but I wonder what you guys and gals think is the best features of the Drakes..... Thanks Russ K5ZZR (licensed since 1964)

All I can say is that its an excellent receiver. Does
not have quite the selectivity of the mechanical filter but
its selective enough. It also has an excellent noise
blanker. This is important because when a receiver has a
fast-attack/slow release AVC it can be desensitized by short
noise pulses. An ordinarly noise clipper has no effect on
this beause it comes after the AVC detector. The blanker in
the Drake eliminates the problem without having any effect
on the desired signal. Plus its a quite good CW receiver and
has good audio.
Drakes are not built to the near military standard of
Collins but that does not affect performance and they were
built well enough so that they still survive and are
supportable. Drake used good quality parts.
If you ask about the T4XB transmitter, its specs are
better than Collins and it meets them.

Russ -

The R-4 through R-4B are pretty much the same receiver. Each succeeding model replaced a few more vacuum tubes with transistors. Actually there's not a whole lot of difference between the 2-B and the R-4 either! The 2-B used a pretty conventional L-C oscillator / tuned IF at 3.5 - 4.1 MHz with a crystal controlled HFO in front of it to a 455 kHz IF and then down to a 50 kHz IF with an L-C passband tuner. The 4 series all use a PTO mixed with a crystal oscillator to develop a "premixed&" injection signal for the first mixer to an IF of about 5.6 MHz. That is then converted down to a 50 kHz IF with the same L-C passband tuner From that point on, however, they are all pretty much the same functionally. The Passband Tuner has approximately a 2.8:1 shape factor on SSB and almost 6:1 on the 400 Hz CW filter. Dial calibration is a single disc with 25 kHz marks and one kHz marks on the knob skirt. The PTO is linear and resettability is more than adequate. The R-4 and 13 tube R-4A had a tube type product detector. The 11 tube R-4A and forward changed to a two diode product detector.

The biggest difference came with the R-4C. Here you have the same basic receiver, but with 5.6 MHz IF crystal filters with a 1.8:1 shape factor on SSB and 500 Hz CW. The audio output stage IS solid state, but it is also Class A, so none of the crossover distortion of the more typical Class B audio amps. Drake DID make it a little TOO hi-fi, so there is a hiss level, especially with phones. A simple two capacitor mod resolves that. The R-4C_used_ to be found on the market with all filters and the noise blanker "accessories" included. The E-Bay mentality, with separate "auctions" for the receiver, the noise blanker, each filter, the manual, the line cord... (well, not the line cord, it's attached!,) has put an end to that. It's only a matter of time before the tubes are yanked for the same treatment. The 2.4 kHz filter is "attached", and so you could add a 500 or 250 Hz Drake filter or others from InRad for CW use.

The dial calibration is a geared two disc system with one kHz marks on the second dial disc, and no markings on the knob skirt. Same PTO and resettability is about the same as with the knob skirt. There are a bunch of mods for the R-4C, primarily from Sherwood Engineering, most aimed at improving the IM performance of the front end with narrower (600 Hz) roofing filters in place of the stock 8 kHz, but at the cost of metalwork and relay switching, and an IC based product detector or, power supply mod, and audio output mod. Unless you are planning a multi-multi station with the inherent IM problems, not worth the effort or money in my opinion.

By the way, the R-4 will transceive with any T-4 and vice versa.

So.... For general band crawling in today's (generally) less crowded bands, the A or B series is fine. I personally prefer the wider slope on the L-C tuner over the sharp crystal filters. I get claustrophobic with narrow filters. I prefer to hear what's going on around me, at a reduced level, and let my ears do the filtering. This is no doubt a product of my first BC-454 surplus receiver which with it's 1415 kHz IF strip LET me listen to the entire 50 kHz of the 80 M Novice band without moving the tuning knob! For contesting or other high density operations, it's nice to be able to switch in a 500 or even 250 Hz filter. You can

even hear the DX station amongst the "policemen".

As for a comparison with Collins, mechanically the Collins is beautiful. Machined metal parts, turret tube sockets, teflon wire, etc. BUT the Collins sold for approximately 50% more than the Drake. At least up until Collins went berserk under Rockwell and discontinued subsidizing ham gear with their military sales. From a functional standpoint, neither I nor the other station can tell if I'm using the Collins or Drake. There is a story that an early R-4 was purchased by Collins. Inside the PTO housing was a note saying something to the effect of ... Pretty slick, huh Art?? (Signed) Bob Drake.

I have owned / own at least one example of each of the above, starting with the 2-B in 1961. Currently my B and C Lines are each on their own desks, and the S-Line is on the shelves with the backup B and C Lines. I keep saying I want to set up the Collins again, but the 200 kHz wide bands and limited additional band coverage (I can't spend an additional $500+ for the privilege of having the ($30) extra crystal deck,) keeps putting me off.

Richard,

For some reason that I can't articulate, my favorite receiver of all time is the R-4B. The gear in my shack consists of the TR-7 Transceiver with remote VFO, external speaker and PS-7 power supply, R-4B + T-4XB _ power supply/speaker, 2B receiver, SPR-4 receiver, FS-4 synthesizer, Yaesu FT-857D (plus a ridiculous number of boat anchors stored in my shed awaiting their turn on the work bench). I used to have a Collins 75A-4 and operated the S line at a radio club.

The best receiver to operate, in my experience, is the R-4B even though it's a pain to go from end to end of the bands, requiring many twists of the wrist. Using an auxiliary crystal I've operating on the 30 meter band, and that's really a pain to tune to the far end of the band, but worth the effort. The R-4B L/C filter, as Gary/K4OAH wrote, has softer, wider skirts than the crystal filters but gives really great results used with the passband tuning.

I wish I could explain, even to myself, why I like operating the R-4B over all the other gear that I have and have used; it's a mystery, like "love," but so far I cannot.

The Drake B Line is fairly easy to work on and repair, especially with the help of the K4OAH CDs, well worth the investment. The Collins gear is also very repair friendly, having been laid-out and designed by a mechanical engineer, Art collins. With the exception of its inherent "noise," the 75A-4 is also an awesome receiver; S line is less noisy.

Either choice is good, both are "top drawer" machines - the best solution might be to sacrifice and get both!

I got the B Drake twins when I got my license back after many years. I am not sure why I had the impression they were the best choice of the affordable equipment but some memory of the old days told me that. I was right, I think. My receiver had few problems but I had to struggle with the transmitter until I got Gary's disc. I discovered from the picturs that the balanced modulator was wired wrong. Probably from someone who had worked on it before because it was also modified with a standard RTS jack for the microphone (which I've left). Its not hard to work on although rather crowded. I also installed the Heathkit Shop mod to the AC-4 power supply.
I think Drake made some compromises to the design of both to get the price down but the performance was not compromised. In fact, the specs are better than the Collins S line except for the mechanical filters in the receivers and from what I read on the Collins reflector I think Drake may be more trouble free.
When Drake came out it blew Collins out of the water because the stuff worked as well or better and was perhaps half the price.
I also have a Kenwood TS-520S rice box. This is a nice tranceiver but is strictly an SSB rig. Although it will do CW its pretty much for emergencies. The Drake twins are actually very good for CW.
I also have a modified R-388. Its a very good receiver but in practice is not as selective as the R4B and does not have the noise blanker.
I have lusted after a 75A4 since they came out. Perhaps I will eventually find one but from all reports the R4B is a better receiver.
What I need now is a good antenna. This is mostly a matter of talking my landlord into letting me do it. Perhaps an appeal to homeland security would do it.

Thank everyone so far for their great insights and experience stories. I'll be going to the Green Country Hamfest on the 11th and 12th of March and feel that I'll come across the one receiver that will jump out and say take me home.... Kind of like going to the animal shelter for a rescue.. Hi K5ZZR

5057. Replacing the Power Supply Electrolyic Filter Capacitors, The Brute Force Way

I almost take back what I said about the R-4B being repair-friendly : received the recap set from Hayseed Hamfest today - the new electrolytic can is beautiful, it sparkles.

Taking out the old, original wasn't a piece of cake - getting the connections off was easy but then I realized that two of the tabs were soldered to the chassis in places without acces - after 45 minutes of head-scratching/hair pulling realized it will take BRUTE FORCE.

Disconnected and moved slightly the phone jack and the boad adjacent then sawed for about 10 minutes with a short blade, all on the top side of the chassis - got to the point where the "stuffings" were easy to pull out - then with a massive pair of vice grips ripped the old can off the chassis - came clean as a whistle, no scratch marks! amazing. Then a rat-tail file cleaned up the rough solder edges on the under side - the new can went in smooth as silk.

Have to get and connect a 1KR resistor between the two tabs then we're done - not easy getting BIG solder blobs off the chassis in deep, crowded spaces/volumes using a small tip iron.

#1 rule if you gonna work on toob stuff. Acquire the biggest baddest Weller or Wen solder gun you can afford and go for it. Steel and copper plated chassis love to be soldered to. It's natural.

You and I were replacing new Hayseed PS caps at the same moment in time. In my R-4B, two of the four tabs were unsoldered. I first bent the unsoldered tabs back to the center. I have a Weller 140W/100W gun and it's still a lightweight for chassis work. There just no way that gun will melt solder on the chassis except for a very small portion near the very top. And even then, the chassis heat sinks too rapidly.

I ended up cutting the soldered tabs but that required some sweat too. After about 15 minutes, I had the old cap out and the new one installed. I am now 90% finished with my Sherwood PS and audio amp mods. On the R-4B, this has turned into a complex job and not nearly as seamless as it was with the R-4C. For one thing, I am trying to eliminate as many heat-producing voltage dividers as I can. Three locations in the R-4B require +12V. That drop will now accomplished with a 7812 on the new Sherwood PS board. But, decoupling the +12V rail is critically important to achieve adequate isolation from one circuit to another.

One other thing I realized last night: One side of the 12V filament secondary supply is grounded. It looks like it was to establish the DC return for the half-wave rectifier (D16, C192) going to Q8. Since the Sherwood board uses a full-wave, CT rectifier for the 7812, I am thinking about moving the ground point from the end of the secondary to the filament secondary CT connection. That should still keep the 6V and 12V tube filaments happy while correctly supplying AC to a full-wave CT rectifier on the Sherwood board.

Just got K4OAH's CD. Wow, the diagrams are crystal clear with much extra useful information. $$$ well spent.

For boatanchor chassis soldering work, forget about puny soldering guns. For one thing, their tips are too small. Get a heavy duty iron from American Beauty, such as this:
:
http://www.americanbeautytools.com/site/models/si/16

Sure, they cost a bloody fortune, but if you restoration work, they're well worth the investment. Big irons often appear on eBay and can be a relative bargain if bought there.

I use a Dremmel tool with cutting disc to cut the old capacitor ears off the chassis. I have never had a metal filing problem as I take caution of this possibility. (Not much metal to cut).

The BIG iron works better than a gun because of the tip mass. Even a big gun has very little tip mass and cools down as soon as it touches the chassis.

It's possible to get them out with a gun, solder sucker, solder wick, and patience. It helps to grasp the can and wiggle it while hot to crystallize the solder (cold solder joint).

It's a good idea to just clip the leads off the terminals. As we all know, the wire Drake used has insulation that will crawl back in a hurry with heat. Be sure and use a bigger iron for soldering the wires to the new terminals as well. The best way is a good, HOT iron so you can heat the joint in a hurry, melt solder, and get off quickly! A smaller iron is definitely a handicap.

Also, I wrap aluminum foil over wiring in the area as even radiated heat from a big iron can melt wire insulation, not to mention actually touching something!

From: Galassi
Topic: 5064 Message: 5064

Good evening, I was listening to a difficult dx station on 5020 kHz, the 60 meters tropical band (Niger) and that's what I get when the preselector is untuned using SSB (ECSS mode).
On AM there isn't any audible noise , but because it is white
The noise is not modified by the PTO, wideband over the full HF spectrum and same with unplugged aerial.
I suspect that maybe one answer to my R-4B S-meter S4 minimum reading? I really don't know.
You can download the mp3 file here, better to listen with the phones (noise at 25" and 40").

http://www.sendspace.com/file/1089bn

Thank you!
Giampaolo

Giampaolo -

I'm not certain, but I suspect you are hearing one of the many multiple harmonic/beats of the oscillators in the receiver. This is a 'no-fly' zone in the Drake 4 Series receivers because of the circuit topology. The BFO is running at 5.595 MHz, the PTO is running somewhere between 5.455 and 4.955 MHz, and the BFO is at 50 kHz. All of these signals 'mix and match' in the 5 MHz region. For example, say the PTO is at 5.070 mixing with the BFO at 50 kHz results in a signal at 5.020 MHz. Perhaps not a good example, but you get the idea. The ones that don't 'move' with the PTO can be something like 5.595 mixed with 50 kHz can produce a response at 5.545 MHz. Of course none of these signals are modulated, so present as 'white noise' in the receiver.

5066. REDUCED: Drake TR3 Transceiver

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-05 14:15:35 UTC
From: Bry Carling
Topic: 5066 Message: 5066

FOR SALE: Drake TR3 Transceiver

The R. L. Drake model TR-3 is an SSB-CW-AM transceiver designed for the transmission and reception of upper and lower sideband signals on the 80 through 10 meter amateur bands. AM and CW capabilities are included.

Ideal for both fixed station use in conjunction with the model AC-3 or AC4 120 volt AC Power Supply, or for mobile installations using the DC-3 or DC4 12 volt DC Power Supply.

The 300 watt PEP input on SSB enables the TR-3 to give an excellent account of itself barefoot and it will drive the highest powered ham linear amplifiers.

Upper and lower sideband selection is accomplished by switching between two Drake designed and manufactured 9 MC crystal lattice filters with 2.1 kc pass-bands. Among the other features included on the TR-3 are VOX and PTT, shifted carrier CW, separate RF and AF gain controls, linear permeability tuned VFO with vernier scale, transmitting and receiving AGC, and separate receiver S-meter and transmitter plate ammeter. The addition of the accessory RV- 3 remote VFO speaker combination enables the operator to receive, transmit or transceive throughout the band being used without disturbing the setting of the TR-3 tuning dial. This is useful for working DX stations operating outside the United States Phone Bands, or for working near your own frequency in search of a clear spot under crowded band conditions.

FREQUENCY COVERAGE: Full coverage on all amateur bands 10 thru 80 meters, in seven 600 k c ranges ; 3.5-4.1 mc, 7.0 to 7.6 mc, 13.9 to 14.5 mc, 21 to 21.6 mc, 28 to 28.6 mc, 28.5 to 29.1 mc, 29.1 to 29.7 mc.
bullet LINEAR PERMEABILITY TUNED VFO: Tunes 4.9 to 5.5 mc for all ranges, 9 mc I.F. minus VFO range overs 80 meters, 9 mc I. F. plus VFO range covers 20 meters. VFO and crystal oscillator heterodyned in premixer for 40, 15, and three 10 meter ranges.
bullet
DIAL CALIBRATION: 10 kc divisions on main tuning dial and interpolation to 1 kc on tuning knob skirt . Effective length of circular dial scale is over 14 inches.
bullet
FREQUENCY STABILITY: High stability permeability tuned VFO tunes same range on all bands . Drift is less than 100 cycles after warm-up, and less than 100 cycles for plus or minus 10% line voltage change.
bullet
FRONT PANEL CONTROLS:
bullet Main Tuning has fluted knob with adjustable 25 division skirt. Tunes VFO and rotates main dial.

bullet RF Tune tunes the RF circuit common to receiver RF amplifier and transmitter driver stages. 0-10 scale.
bullet Plate and Load tuning adjust pi-network capacitors in transmitter for proper resonance and loading on each band.
bullet Band switch selects desired ham band (see frequency coverage).
bullet Function switch has four positions CAL, SSB, X-CW, X-AM. CAL operates built-in 100 kc crystal calibrator for accurate setting of main tuning hair line indicator and knob skirt SSB provides SSB operation, either VOX or PTT, and is receive position for SSB, CW, and AM. X-CW (transmit CW) inserts carrier , converts `Xmtr Gain´ control to carrier injection for tuning and CW transmitting. X-AM (transmit AM) inserts carrier and screen modulator for AM transmitting.
bullet XMTR GAIN functions as mike audio gain on SSB and AM, and as carrier injection control on X-CW for tune and CW.
bullet RCVR GAIN knob controls receiver AF gain and power ON-OFF switch. Lever behind knob controls setting of RF gain.
bullet Sideband switch in conjunction with indicator lights marked Upper and lower selects desired sideband by connecting into the circuit either the upper or lower sideband filter.

There is no power supply with this radio.

Topic: 5069 Message: 5071

The JR-599 is the same as the R-599 (Kenwood)...Trio became Kenwood..it was a very good receiver, ham band only except for the WWV band which covered 9.5- 10 Mhz as I recall. .25 microvolt sensitivity..decent selectivity as well. This was the first one, they later came out with a R-599A which had a different dial setup, planetary drive like the R-4 series and some other improvements...these could come with the optional 6 and 2 meter IF convertors making them also covering those bands...the nearly impossible-to-find connecting cable to the transmitter is the trick.... the connector is also weird, military or something..

Hello Bill,

The Kenwood Twins (599 receiver and transmitter) have a good
reputation, and are still popular. You can get all the info
you want on the Kenwood list.

5072. A couple of TR-4 questions

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-06 20:09:17 UTC
From: Fraser
Topic: 5072 Message: 5072

I have a TR-4 back into working condition. I have not yet attempted an alignment, but I can receive and transmit.

I only have a 100watt slug for my Bird43, but when connected to a dummy load, on CW I can easily get over 100watts and the same when whistling into the mic (Shure 450). However, when speaking, even close to the mic and in a fairly loud voice, I can barely manage 15 watts on peaks. That just doesn't seem right?

And finally, how many turns should the Carrier Balance control have. Mine seems to go on forever...

Thanks for any help.

Fraser, W3UTD

5073. File - Bi-Weekly Statement

Topic: 206 Message: 5073

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

Hi Fraser,

In my experience reading the wattmeter while speaking is an exercise in futility. The meter can't respond quickly to the peaks and valley in speech. A regular scope or monitor scope is much better for what you're trying to see. I have an old Heathkit IO-10 and its great for this.

The carrier balance control will have an infinite number of turns. The shaft is on ball bearings, but doesn't have a mechanical stop, and will slip once it reaches either end.

Bill

Fraser -

Probably nothing wrong. Average power doesn't move meters much, plus the meters on the TR-4 are sluggish. Add in the meter damping on your wattmeter and it's tough to get them to show much. You really need a peak reading meter or scope to 'see' peak power on SSB. The cheapest, oldest Heathkit or other scope is fine for monitoring. You didn't mention where the MIC GAIN control is set on the TR-4. The ALC won't let you over-drive it, so don't hesitate to turn it up. There's a possibility that the mic is 'sorta' bad, but it IS high impedance, high output, so if it works on other rigs it's just fine.

The Carrier Balance pot is a 10 turn variety, AND has no stops at either 'end'. It's a 'ball drive' so slips pretty easily. If you turn it 15 or so turns in one direction, and then turn it back 5 turns, you'll probably be near the center.

Thanks for the insight, I guess I was being too conservative with the mic gain. I turned it up and made about 30 contacts at the end of this evenings SSB contest on 20m and 40m, so I think I'm good to go.

Michele -

The lower limit on the Preselector (RF, Mixer and PreMixer) stages tuning is slightly below 1.8 MHz. Adding a crystal will get you 'some' BC stations, but at greatly reduced levels.

The "correct" approach is with an up-converter like the Drake 2-LF, a passive mixer that upconverts the 0.5 to 2.0 MHz range to 28.0 - 29.5 MHz. Not a difficult circuit to build, merely a packaged DBM and a crystal oscillator at 27.5 MHz.

5088. spot position on T-X4C

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-08 14:26:37 UTC
From: wb2kki
Topic: 5088 Message: 5088

When I try to spot on my T-X4C it trips the antenna relay and mutes my RX as it should in the TX mode.

Problem is I can't hear the beat note even when I unmute the rx.

Is there a mod for this and is this the the way it is supposed to work?
You would think it would not engage these things in spot mode so you can hear the beat note.

Thanks!!
Mike

Michele -

There are several. There is the Drake FS-4, which was the original product. Quite complex with multiple semiconductors as was typical for the day.

There was a homebrew version of a 'Frequency Synthesizer" in Ham Radio, August 1972, by Stein.

There was a further 'integrated' PLL version in QST by Hageman in June 2004.

The Woodbox DDS-4 was a DDS (9851) based unit in 2004 from an Italian company that was too expensive to survive.

There are several little DDS based 'VFO' kits (N3ZI) that could probably be adapted.

Probably more, but that's all I can think of. So yes, there are options.

SPOT mode does trip the antenna relay, but it should NOT MUTE the receiver.

The low level stages are keyed, just not the PA.

In SSB, both units must be on the same SIDEBAND.

Most likely the problem is in the TRANSCEIVE switch and will be 'fixed'
by judicious application of DeoxIT. It's certainly the place to start!

Topic: 5084 Message: 5092

I believe Floyd, K8AC designed his own DDS VFO rendition for his TR-7 that looks like it could be adapted to the 4 series. He's got a lot of useful information on his website. Keep in mind that some early PLL synthesizer and DDS designs are plagued with spurs and relatively high levels of phase noise.

A hybrid option is to use one of the frequency counters made for the Drake units and use a K4DPK VFO stabilizer. I have a pair for my C Line, but have not tried them yet.

The rx mutes because I have it connected to the same relay for the antenna
switch.

I overcome this by changing the mode switch to operate (for beating) on the rx
but still can hardly hear the beat.

So the sitch is working Ok.

The T-R relay in the T-4X has a pair of contacts that MUTE the receiver
by opening in TRANSMIT (or SPOT) and switches the antenna from the
transmitter output to the receiver input.

In SPOT mode, those MUTE contacts are shorted by a section of the
TRANSCEIVE switch when it is put in the SPOT position, switching the
antenna, but NOT muting the receiver.

5095. Re: [DrakeRadio] spot position on T-X4C

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-08 18:26:45 UTC
From: Michael Shelly
Topic: 5088 Message: 5095

Thanks Garey!

Mike

From: Garey Barrell <k4oah@...>
To: DrakeRadio@yahoogroups.com
Sent: Tue, March 8, 2011 1:17:22 PM
Subject: Re: [DrakeRadio] spot position on T-X4C

The T-R relay in the T-4X has a pair of contacts that MUTE the receiver
by opening in TRANSMIT (or SPOT) and switches the antenna from the
transmitter output to the receiver input.

In SPOT mode, those MUTE contacts are shorted by a section of the
TRANSCEIVE switch when it is put in the SPOT position, switching the
antenna, but NOT muting the receiver.

5098. Re: [DrakeRadio] R4C on medium waves ?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-09 19:03:39 UTC
From: Charles Ring
Topic: 5083 Message: 5098

Using the crystal for 160 meters, I can get down to I think 1390 Kc
before the preselector bottoms out, and to 1330 with reduced sensitivity.

From: Gary
Topic: 5083 Message: 5099

All true, BUT, if you just want to listen to the local AM stations,
they are really strong and you get excellent reception down to at
least 1.0MHz. It may depend slightly on your R4 alignment, you may
be able to "re-align" it to go a little lower.

5100. FS DRAKE RV-4

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-11 19:27:07 UTC
From: Kris Merschrod
Topic: 5083 Message: 5100

DRAKE RV-4 (Detailed Photos Available) Asking $120.00

The remote VFO is a nice accessory for Drake Transceivers. It provides a speaker and a place for the AC-3 or AC-4 power supply, plus it allows split operation for the TR-3 or TR-4 transceivers.

This is an early RV-4, two-tube version (OA2 and 12AU7; Serial Number 15039 - early 1973). Later models were single tube. The faceplate is very clean and has the silver trim around the perimeter. Later models did not have the silver trim. The cabinet is dull and scuffed in places. The rear feet are not original. The chassis (copper plated) has the usual "freckles" and underneath in one corner it is "rusted."

I have tried to use it with my late model TR-4CWx; It only works in one position, and I can't figure out why. It seems to attenuate the reception and the transmitted signal.

Although the original speaker is included, I have installed a new 4 ohm speaker for a better sound. It will be well packed. Buyer pays actual shipping (Approximately $15 Stateside).

Topic: 5102 Message: 5102

You can look them up, on a plethora of threads, in the discussion forums on QRZ, QTH, eHam and others. This is Martyn Allison. The same guy who ripped off my friend Allen, and caused Allen to not want to do business with eBay ever again. Allen sold him a perfectly good used radio, for a recently deceased ham's wife. Allen is a very knowledgeable guy, and checked the radio thoroughly, before shipping it out. It had one display light burned out, that he mentioned to the buyer. The radio was raided of parts, then returned, making a big stink about the missing parts, which HE took. Allen was left with costs associated with repairing the radio, and a bad reputation on eBay, which is totally due to this action.
He did me wrong, in selling a supposed "Mint" Drake AC4, that turned out to be in FAR less than perfect condition, and had a taped up, leaky electrolytic capacitor, laying loose inside the case. He told me that his "Technician thought you might be able to use this, so it was thrown in". Inside the case? What use would I have for a leaky electrolytic? He has a high feedback score, due to eBay's way of calculating feedback scores, but look at the comments, under his actual feedback, and you'll see that it is common for this guy to "pull a fast one" on unsuspecting buyers and sellers. I had a couple of heated exchanges, with him, when he made obvious misrepresentations of radios he was selling. I don't know why they sent me this. I must have been in his address book, and they sent it to everyone.
This guy is the reason for the old Latin phrase "Caveat Emptor", or Buyer Beware. He is a ripoff artist. We all need to look out for one another, and make sure to inform everyone we know, about guys like this.

This is "Radio-Mart". I thought all people on these lists knew about him.

He shipped me a Heath HM-15 that was not the one in the photo. Before ebay changed the feedback he had very bad feedback.

When I gave him negative feedback he gave me negative feedback in retaliation. He cannot do that anymore.

If I see his name on a listing I just forget about it.

Good ole Martin. He is a piece isn't he.

Luckily, I've never bought anything from him but I have sold to him. He's bought items from me off of Ebay under Radio-Mart or his other alias "GottaHaveit". Let everyone know that he commonly practices "shill bidding" with his auctions by having his buddies bid up his equipment for him. Last year, he bought a mint Kenwood 2M all mode transceiver from me that I sold on Ebay for the widow of a SK. I thought to myself "I wonder how long Martin will sit on this purchase before he relists it on Ebay again". It only took 2 weeks before Radio-Mart listed the item. I laughed.

Martin is a cheat and anyone who buys from him better be ready to be disappointed.

Bob,
Me too. I avoid him like the plague. At one point, I thought he was running a legit business, selling collector quality stuff, then 3, or 4 years ago, I bought that AC4 from him, and my thought of him being legit, went right out the window, into the gutter. My friend, Allen, sold to him, before letting me know, who the buyer was. Frankly, I never thought of how to scam a seller, like that, and probably would not have told Allen anything other than my experience as a buyer. These kinds of folks are a scourge on our community, and we need to do the email equivalent of a "Blanket Party" on them.

I've never heard of Martin, then again, I've never done any buying and selling of radio stuff on eBay. But I do have a fair bit of experience with eBay, having worked for a dealer who traded in vintage and high-end guitars. He was regularly accused of shill bidding also, but didn't do it. The high-end guitar market is a pretty small one, with a number of the same folks bidding on a limited number of guitars...probably similar to the ham radio market, which is even smaller, which could tend to make some bids look like shills that aren't. That was the case with us.

That was our basic business plan. We would find instruments (most often on eBay) that had poor descriptions, poor photos, or just depressed prices for whatever reason and buy them. It was usually two to three weeks before we had re-photographed (that was my job) and re-listed (usually with better write-ups) the instruments. I remember one item I wrote up (because those instruments are my specialty and even more of a niche item) that had languished on eBay with no bids at an opening price of $5k due to a poor writeup with spelling errors and fuzzy photos. We bought it for that on a snipe bid, and within a week or two I had re-photographed the item and re-listed it with a great description. It sold within 12 hours of our re-listing for a BuyItNow of $6k to a collector in Japan. We didn't usually make that kind of spread that quickly, but we were quite active on eBay, both as a buyer and a seller. And took a lot of flack for it on various online forums.

Like I say, I don't know Martin at all and certainly won't vouch for him, and if he is the cheat he seems to be, I hope no one here gets burned. I'll be sure to watch out for him and be careful, as I am starting to watch eBay for radio gear - casually looking for a T4X (to marginally bring the thread back on topic!). But I did want to point out my experience working for a very visible eBay dealer.

As an aside to this thread. Here is a great URL to check the feedback of any eBay user:

www.toolhaus.org

I have used it many times over the past few years to see just what particulars buyers and sellers were most agitated about concerning their transactions. Mr. Allison has quite a list.

Yeah, agreed!
I have thrown a bid or two his way on e-bay. He always has really nice looking stuff. I had noticed bidding was always pretty high too. Too high for me. Now I know why and am glad I didn't win....er...lose.

I had heard a comment about him here or there but I try not to judge too quickly. First hand reporting like this is valuable info. Thanks guys for sharing.

Except for an old Shure mic that turned out to be a piece of junk and a Icom R-71a receiver that the seller pulled the stock filters out of (high demand models), the only really bad experience I've had on the net was thru QTH (no fault of the site) trying to buy a SB-220 amp. Sent a $550 money order and never heard from the guy again. Learned to always use USPS money orders from that experience. Doing so makes that fraud a federal offence. I learned too late. Now-a-days I only use Paypal on big dollar items.

God bless

At one point, I thought he was running a legit business, selling collector quality stuff, then 3, or 4 years ago, I bought that AC4 from him, and my thought of him being legit, went right out the window, into the gutter. My friend, Allen, sold to him, before letting me know, who the buyer was. Frankly, I never thought of how to scam a seller, like that, and probably would not have told Allen anything other than my experience as a buyer. These kinds of folks are a scourge on our community, and we need to do the email equivalent of a "Blanket Party" on them.

From: fredwegener
Topic: 5111 Message: 5111

I'm trying to go through the injection coupling alignment on a TR-4. The manual calls for a .005pfd cap in series with a 1k resistor to be used from different tube pins to ground during the course of this alignment. This has got to be a misprint. Did they mean .005 microfarad? That would make more sense!

Thanks, Fred AC5TF

Lee, as a capitalist, I have no problem with someone who finds a way to buy low and sell high. That is the essence of capitalism. To be able to do it in the same store, where you bought it low, is odd, but not unheard of. One friend of mine buys and sells the same "scrap gold" on eBay, all the time. No problem.
Shill bidding is an iffy thing. Sometimes it may appear as if there is shill bidding going on, when there isn't. Other times there may be some form of that, by a seller having a friend "get the bidding started", or "over the hump of the reserve", and that, too is not so nefarious. Not very honest, but not nefarious.
But, this guy, Martyn, has so much negativity floating around about him, that doesn't involve these things, that one must conclude, "Where there's smoke, there is a fire" and he obviously is doing something with a fraudulent intent. Then, add in the accusations of shill bidding, and buying trashed radios, and reselling them as ***PRISTINE*** or **MINT**, One Owner, Non-Smoker, from my personal collection, or any other non-factual statement, and it is easy to see, just how crooked this guy is. Check some of the threads on QRZ and QTH, about him, and his fraudulent business practices.
Here are only a few, of the myriad commentary threads on the usual websites:
http://www.eham.net/ehamforum/smf/index.php/topic,6231.0.html
http://forums.qrz.com/showthread.php?285109-Radio-Mart-Martyn-K4TEC-Gone&p=2199206#post2199206
http://forums.qrz.com/showthread.php?285196-Curious-Situation-With-Our-Ol-Buddy-R-M-Over-In-Kentucky
http://forums.qrz.com/showthread.php?278402-New-RADIOMART-identity&highlight=radio-mart
http://forums.qrz.com/showthread.php?276482-Radio-Mart-now-licensed!&highlight=radio-mart
http://www.vr2xmt.com/ebayconradiomart.html
I was personally involved in a bad transaction, with a misrepresented item, and gave him neutral feedback, to avoid him hammering me with negative feedback, back when sellers COULD give negative feedback. So, in that respect, I guess I was part of the problem. I helped perpetuate his dishonesty, and therefore I am simply trying to make up for that mistake, by notifying folks of his crooked ways. I may urge people to not buy, but they will do, what they will do, and as long as they do so fully informed, I can do no more. While I harbor resentment over what Marty did to me, and my friend, I have no other legal recourse, at this point, so I use this method as my way to help deter folks from getting ripped off by Marty.
Again, Caveat Emptor.

George,
Yes, I have made purchases from them. I bought parts for a Heathkit Marauder from him, as well as a very nice Ham III rotor and microphone, in another purchase. I seem to think I got my National NC-300 from him, too. Most recently I purchased his blue LED kits, for my Drake 4-Line stuff, and some spare feet. His stuff was well described, reasonably priced, shipped rapidly, and packed well. I would happily do business with him in the future, if need be.
I believe you will be happy as well.

Leaving no stone unturned I recently needed a set for a 4 line and just used the red white yellow cables commonly supplied with every vcr ever sold. Worked fine. I tested these by comparison to some RG58 of same length and found them identical capacitance.
Anyway, not elegant but cheap. Like computer power cables they seem to multiply in the junk box at night. Plus, I like how flexible they are compared to others. And, I like the rubbery plugs.
YMMV. Just what works here.

I must admit folks, that I did the same. I used some heavier duty stereo interconnects, that were laying around, from my days before using my computer as a stereo. The interconnects made by Monster Cable, work well for me, but if you have to buy some, they would be awful pricey for use in George's situation. I believe some standard interconnects of good quality would be sufficient. My initial reply to George, was simply an endorsement of the business which he had chosen. They do good business, was all I was saying.
But, if I were to need more interconnects for my "B" or "C" Lines, I would simply use those leftovers from the component stereo system.
One caveat though, I was told when I had Jeff Covelli work on my "B" Line, that it is best to make all adjustments with the same cables as you will be using in actual use.

This question has been covered many times on the Drakelist reflector. Here is the best-informed answer on the Drake cables, from Garey Barrell:

"The original Drake supplied cables were all standard "microphone" shielded wire, with the exception of the "INJ" cable. All but the INJ cable were similar to what is used in audio patch cables today.

All cables were 38" long tip-to-tip.

The INJ cable used a foam inner dielectric and phono connectors with a white insulation. This cable measures 60 pF total capacity.

All other cables used the standard for the day clear polyethelene inner dielectric and phenolic (brown) insulated phono connectors and measures ~100 pF.

Original Drake INJ Cable = 19 pF/ft = .160" o.d. (foam poly)

RG-62 = 93R = 13.5 pF/ft = 0.240" o.d.
RG-59 = 75R = 14.8 pF/ft = 0.242" o.d.
RG-6 = 75R = 16.2 pF/ft = 0.270" o.d.
RG-174= 50R = 30.8 pF/ft = 0.110" o.d.
Mic Cable (Belden 8410) = Hi-Z = 33 pf/ft = 0.160" o.d. (foam poly)
Mic Cable (Belden 8421) = Hi-Z = 16 pf/ft = 0.180" o.d. (foam poly)
R/S Audio Patch Cable = 28 pF/ft = 0.165" o.d. (poly)

The best choice is the Belden 8421 Audio cable from their "Brilliance" line. It looks just like the other cables, and is very flexible. The RG-62 is OK, but it is 50% larger and far less flexible. RG-62 is also prone to shorting if bent over too small a radius. The only pertinent factor is the total capacity, impedance and "loss" are not important.

Actually the standard R/S audio patch cable will work ok in the INJ role as long as the Injection alignment is done with the R-4 and T-4X cabled together.

The C-Line can use the same cables, except there are two cables (INJ and CAR OSC) that need to be low capacity. The ANT lead should probably be RG-58 coax, but it's really not long enough to be significant.

When I acquired my used T4XC years ago, and Drake was still in the ham gear business, I called and talked to Bill Frost because I needed the interconnect cables. He advised that audio cables were OK for ALL the connections. I did make up a set of RG-59 cables for injection recently and an RG-58A/U cable for the antenna, but only because it made me feel better! The RG59 was a heck of a lot cheaper that RG62, and only a very small increase in the capacitance per foot.

Just my $.02!

YES!

You are free to use old twisted pair telephone line between units if you like.! The pair WILL work as long as you don't have too much RF floating around the shack, it takes only two wires to ring a doorbell.

However, reasonable quality shielded 'phono' or 'video' cables will give a little higher likelihood of successful operation. The 'video' (yellow) cable of the triple sets is even a little lower capacity and would be best for the INJ.

IF you intend to transceive with the pair, they should have the INJ trimmer adjustments made while cabled together with the cables you intend to use. Drake of course did not have this option available at manufacture as the units were sold separately and there was no practical way to ensure that pairs were kept together.

IF you intend to transceive, and want to do so at full power and maximum receiver sensitivity, with a minimum of peaking and re-peaking, then you need a decent (low capacity) INJ cable. As in just about all cases, I've found that Drake's engineers were more than competent. If you 'drill down' through something that seems un-necessary or doesn't make sense (to you), you find that there WAS a sound engineering decision behind it.

So... IF you don't intend to transceive, or don't mind having to retune each time you switch in or out of transceive, or just don't care about the best performance from your radios, knock yourself out! :-)

From: arsnf7z
Topic: 5129 Message: 5129

early in my flying career I flew antique biplanes. I always dreamed of landing somewhere off the beaten track, only to find some barn with a Stearman or Fleet biplane that had been forgotten about. like new, I make an offer and it would be mine. I suppose others might have similar thoughts, like finding a '57 Thunderbird in a garage, with only a 100 miles on the odometer. hams, like myself, might dream of finding a Drake C-line in someone's attic that had never been used. I have a beautiful C-line but luck was with me and I found that perfect R4C, T4XC, MS-4, AC-4 combo sitting in an attic. never used. well, apparently used once only to find that ham radio wasn't meant for them, so it was all boxed and forgotten about for thirty-five years. the owner has a terminal disease and everything in the attic was being sold.

the C-line is as if it just came off the assembly line, and as you might imagine, I am thrilled. manuals, receipts, cables everything is there. this all started from looking for a R4C PTO to replace the one that drifted far beyond specification. you know how that goes. one thing led to another, and I couldn't let it go when I stumbled upon such a deal. of course, I now have two beautiful C-lines. the R4C I've had for thirty-five years also, is souped up a bit and performs much better than the stock version. just adding a new product-detector and tweaking the alignment made a world of difference. still, it is so nice to feel that smooth PTO on the new units, and see just how blue the lamp-filters were right off the factory assembly line. these were one of the last to be built, and even have 3-prong AC cords with ground. pinch me!

I just need now to find a nice L4B and I'll be done (though I have said those words before).

perhaps it is just me .. but is eBay and QTH.com always so wacky? I've had very good luck with QTH.com until I decided to buy a L4B. the search stretched out for months, and then I found the perfect offering. the small picture looked good enough, though let's be honest .. you can't tell much. so, I asked for a few more details. perhaps a photo and description of the interior. an assessment of the performance? do the 3-500Z's light up? any output? smoke on key-down?

I was told that the L4B was owned by a ham for 25 years and should be in good condition. well, that's a great mantra for the seller, as in 'thou will be perfect in every way', but to the seller .. it's a bit dubious, and so I asked once again for additional photos and assessments. once again, I was give the same out-of-focus photo of the the tuning knob with no additional descriptions or explanations. now maybe it is just me, but before I send someone a $1k, I think it wise to understand what it is I am buying. the seller apparently did not agree .. would not come forth with details because I suspect he didn't know. the amp was somewhere unavailable, or he was simply brokering it for someone else.

I really didn't think it was asking too much, to garner some sense of what I was buying. I guess this is the age of eBay, caveat-emptor, and it's a seller's market. I don't want to come off as jaded, as all my QTH.com interactions have been very positive and resulted in sales. however, I am concerned. is it really too much to give a potential buyer a fair representation of what they might be buying?

I was told it was owned by the same ham for 25 years. the amplifier was built in 1975, and is 36 years old. I don't care where it's been the last three decades, or if it resided in a 'no smoking' shack. egads .. it could be perfect, it could be a worthless pile. as the potential buyer .. humor me. throw me a bone .. don't tell me that there are a dozen other buyers and therefore you don't need to tell me anything further about the amp sitting on someone's table. somewhere ..

what do you think? is this a trend? I recently saw a Drake RV4C on QTH.com for something like $385. get out .. almost as ludicrous as the Heathkit DX-60 I saw for sale for $300. yeah, it has controlled-carrier AM and looks old. oh yeah, it's crystal controlled!

befuddled ...

When I went looking for my L-4B, I ran into the same type of 'elusiveness'. I then 'met' a guy in Las Vegas, who had one that hadn't been used for a number of years. He had decided to bring it back in service and had completely rebuilt the power supply with new diodes and caps. Then lost interest when he acquired a more modern amp. It went 'under the counter' and sat there until I expressed interest in purchasing one. He sent me at least 50 pics when I asked him to do so...we exchanged at least 20 emails about the amplifier and then finally spent substantial time on the telephone. We struck a deal for $1,000.00, which was higher than I had seen other L-4's, but I was very confident the price was worth it. A very good friend lives in Pahrump so I asked if he could take it up there for me....which he did, plus a surprise, a box of at least $500.00 worth of other L-4B parts and tubes..he had saved his take-outs after he had put in 2 new Eimac 3-500Z's. Said they worked, but wanted everything 'new' when he finished. I put them in and lit the box and they didn't even show a little blue, even at idle, which surprised the heck outa me. I didn't however, bring up the power.

When I got the amplifier it was very dusty, but after blowing it out, it was immaculate and works great.

Long story short...keep looking, you will find someone who will spend the time to let you get acquainted with the amp before you purchase..and you can be sure that person probably doesn't have anything to hide about the amp.

The problem is there a lot of people liquidating estates that don't know shit about this stuff. You should be able to tell from the initial listing or at least the first question.

I have been helping to liquidate a collection of antique model airplane engines. Another member of our club writes the descriptions and I do the photos and listings. We have had about 3 problems out of 1200 engines we have sold

A couple of years ago I bought a Drake T4X. The seller was a ham. He had a picture of a power meter on top of it showing full output. When I was testing it I found it had bad 120Hz hum. How about 100% 120Hz plate modulation? The electrolytics in the power supply no longer were! I had planned to put the upgrade kit in anyway.

You just have to be careful.

You are very lucky to notice the "red flags" and to proceed with caution. Any honest buyer will supply pixs and information. I once saw a used L7 from a new ham radio store. I disregarded the red flags and it turned into a nightmare.

First he said he did not have a big box to ship it and would not be responsible for damage, so I shipped him a huge box.

Then he said that he would not sell it unless I sent him a "hold harmless " letter, signed and notarized. I did.
Then he wanted a cashiers check. I mailed it.
Then when a week went buy I callled the store and asked if it had shipped. He said well, I turned it on and it smoked, "you know these drakes do that..."
I figured that he wanted to sell it to a friend. I told him that they just don't smoke but he argued otherwise.
Finally, I had to persuade him to send me back my money or cashiers check.

Use your gut feeling, common sense or what ever. If it looks like a rat, smells like a rat its a rat. And this was from a store and not a private person.
73's al.

ps. I did buy a L4b from a local ham instead. He allowed me to open up everything with nothing to hide.
73. al.

I agree with what others have posted. For that amount of money, the seller needs to make the sale. He needs to kiss your butt, not the other way around. If he has a dozen other buyers lined up, tell him to go for it.

Keep your ear to the ground, you'll find what you want eventually. I'll put this in perspective, it really didn't take me that long to find an L-4B from a local who just wanted to sell it to someone who would appreciate it, in good condition needing minor cleanup. It had been idle for an unknown number of years, and I was allowed to inspect it thoroughly before purchase (but was unable to power it up). The price? $450.00. The RF deck puts out an an impressive quantity of RF with the tubes that were in it. The PS was brought up slowly on 120V and worked fine. The Jones plug on the PS went up in flames when I hit it with 220 volts, but I would never have even thought of complaining to the seller.

Part two is the L-7 from an estate that had a dark tube (unsoldered filament pin) and needed EXTENSIVE cleanup. I've got a net of around $150 in it, but the actual purchase price wasn't much more than that.

Good things come to those who wait.

Topic: 206 Message: 5141

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

5142. TR-4 transmit problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-20 21:44:36 UTC
From: William Houghton
Topic: 5142 Message: 5142

Hi Drake fans,

First let me appologize for asking something that was asked recently. I didn't save the emails on this subject and a couldn't find them in the messages at yahoo groups.

I'm bringing up a non-working TR-4 that I recently acquired. The receiver is working fairly well right now on all except the highest 10m position. That will be the last problem to solve.

When I switch to the transmit mode, the CW-X position, the output power immediately goes to about 100W+ with the XMIT GAIN control fully CCW. Adjusting the bias pot on the AC4 can reduce the plate current from about 500ma down to about 350ma. The weird thing is that when I try to measure the voltages on the 6JB6 pins with respect to ground touching the brass strip that connects pins 2 & 6 of all three tubes together with the positive DMM lead causes the output to drop to zero and the plate current to drop to the idle level. Adjusting the bias can with produce the 100ma idle current with the meter probe touching the brass strip.

Any ideas?

Thanks & 73, Bill, WA6NEQ

When I switch to the transmit mode, the CW-X position, the output power immediately goes to about 100W+ with the XMIT GAIN control fully CCW. Adjusting the bias pot on the AC4 can reduce the plate current from about 500ma down to about 350ma. The weird thing is that when I try to measure the voltages on the 6JB6 pins with respect to ground touching the brass strip that connects pins 2 & 6 of all three tubes together with the positive DMM lead causes the output to drop to zero and the plate current to drop to the idle level. Adjusting the bias can with produce the 100ma idle current with the meter probe touching the brass strip.

Any ideas?

Thanks & 73, Bill, WA6NEQ

Keith,

Yes, there are xtals in all of the positions. I haven't tried the alignment procedure yet. I never seem to hear anything on 10m on any of my radios which is why I'm leaving that for last.

Thanks for the input,

Bill

Subject: [DrakeRadio] TR-4 transmit problem

Hi Drake fans,

First let me appologize for asking something that was asked recently. I didn't save the emails on this subject and a couldn't find them in the messages at yahoo groups.

I'm bringing up a non-working TR-4 that I recently acquired. The receiver is working fairly well right now on all except the highest 10m position. That will be the last problem to solve.

When I switch to the transmit mode, the CW-X position, the output power immediately goes to about 100W+ with the XMIT GAIN control fully CCW. Adjusting the bias pot on the AC4 can reduce the plate current from about 500ma down to about 350ma. The weird thing is that when I try to measure the voltages on the 6JB6 pins with respect to ground touching the brass strip that connects pins 2 &

6 of all three tubes together with the positive DMM lead causes the output to drop to zero and the plate current to drop to the idle level. Adjusting the bias

can with produce the 100ma idle current with the meter probe touching the brass strip.

Any ideas?

Thanks & 73, Bill, WA6NEQ

Bill -

If touching your meter probe to the Grid bus of the PA stops the output,
the stage is oscillating.

If there IS a crystal in the third 10M band socket, remove it and
exchange with the one in either of the other 10M positions. The crystal
may be defective.

If the crystal is missing.... :-)

Bill -

You should be able to hear the calibrator signal on 10M even if the band
is dead!

Swap those two crystals and see if the top range then works.

Don't waste your time on it for the time being.

10M SSB activity is between 20.0 and 29.0. The area above 29.0 is AM and FM.

All,

Thanks for the input.

The transmit problem occurs on more than one band. I specifically remember checking it on 80, 40, and 20. I don't recall if I tried it on 10m or 15m.

The receive problem on the top of 10m. In CAL position I don't hear a strong cal signal every 100KHz. Instead I hear a weak tone throughout the PTO tuning range. I think I'll try Garey's suggestion about swapping the 10m xtals to get a quick sense of the problem. Beyond that, I'll deal with it after I fix the transmitter problem.

73,

Bill

I think you mean 28.0?

Actually, the bulk of SSB activity is between 28.3 and 28.5 (the novice/tech subband), with 28.3 being the bottom of the voice band. 28.400 has become the defacto calling frequency. As sunspots pick up, activity can expand above 28.5. 28.0-28.3 is CW, beacons, and digital modes. The unofficial AM subband is roughly 28.96-29.41, to accomodate CB rigs moved up 2 MHz. 29.3-29.51 is the satellite subband. FM is 29.520-29.690. Anywhere 28.3-29.7 is fair game for SSB according to the FCC rules, but most folks adhere to the bandplans.

Canada's bandplan is a little different.

Possible, especially if the finals are 'mis-matched' brands or condition.

Do you have the PLATE and LOAD controls at '0'? Keying the transmitter
with no drive to the PA, (as in missing or defective crystals,) can make
it sing, particularly if the TUNE and LOAD are up from '0'.

Don -

Yeah, it's standard. Sits on top on the right side just in front of the
Power Transformer. Has the big 100 kHz crystal sticking up! You can
see it in the top chassis photo in the manual.

I figure somebody might have an eBay special where all the filters,
tubes and anything else that 'unplugs' has been removed! :-)

Have A very nice Drake B-line for sale, was just gone COMPLETELY thru
by Wa8saj, The B-line has no operational issues. The cosmetics are a easy 9/10.A coupla of tiny nicks, chassis very nice,paint,origional.
the line consists of the folowing:
1. R-4B,AM,CW and ssb filters.All crystals including WARC and 10 meters.no 30
2. T-4XB, full out.
3. AC-4 power supply, complete rebuild using "Heathkit shop" kit& boards
4. Speaker- MS-4.
5. complete set of NEW interconnect cables.
6. Origional Drake manuals
7. mic adaptor with 1/8" jacks for PTT and MIC input.
Will all be properly packed and double boxed for safe shipment,Fedex insured.
Asking 750.00 split shipping.
can do Pay pal + or usps MO.
thanks

From: xyz
Topic: 5165 Message: 5165

I have a Drake R4C and when I turn the NB or the Crystal calibrator the meter gets peg to the right and there is no audio.
Has anyone come up with this problem?
Any possible solutions to the problems?
Thanks! AE4TO

You need a shorted plug in the MUTE jack on the rear panel.

5167. Drake TR4Cw S-meter suddenly less sensitive

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-28 05:43:03 UTC
From: billykatzz
Topic: 5167 Message: 5167

Folks, maybe it's me, but it seems like as of yesterday the S-meter on my TR-4Cw just doesn't seem to be properly responding to incoming signals. Strong stations that audibly sound S9 or higher barely make the meter move. However, when I put the rig in the calibrate mode, then the needle has a HUGE swing, but of course that's normal.

It just came on suddenly. I haven't changed anything on the rig, but I did change out my MN4 for a MN2000 I picked up a few months ago. Could that be the cause? Anybody have any idea what's going on?

Bill in Pasadena, NK6Q

Slide switch on the side in correct position? (You didn't say if you tried transmitting and if this works ok). Internal relay clean? Internal lamp fuse ok? Check the slide switch first as you could have bumped it.

Lee:

Bingo, you nailed it. Oops, my bad. Last night when I was sliding the MN2000 into place it's cabinet pushed the transceiver's side switch from TCVR to RCVR.

After posting my dilema, I figured maybe something in the MN2000 was affecting the incoming signal, so I disconnected it and pulled it out. That's when I saw the side switch was in the wrong position.

Boy, do I feel stupid.

5171. The Slide switch on the TR-4s

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-03-28 12:45:31 UTC
From: Kris Merschrod
Topic: 5167 Message: 5171

I often wonder how many other hams use the slide switch with a RCVR or mute for another purpose. My R4-C /TR-4Cw combination is a pleasure b/c the quality of the receive is better and more controlable. But, this set up is basically operating "split" so having to reach back there from time to time to make sure that the TR is on frequency while warming up is bothersome. If only it were "up front" some where. The R4-C has an aux ant jack so that the split is also between a RCV and XMIT ants. It is a nice set up.

How do others set up this arrangement?

Dale
R4 and T4X
Condition good to very good
I have had them since they were almost new
R4 recently gone thru. T4 partially done. The can lytic has been replaced to correct a malfunction
Used as recently as a few months ago when they were replaced by C line
$300 the pair plus shipping cost. Prefer to keep together as pair.

Fred
It is a satin black unless it has been waxed and polished extensively or repainted
Some 4 line gear I have (all original) is smooth and some is spatter but all are satin
Krylon 1613 is generally considered the exact match.

5180. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-04-04 07:02:46 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5180

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

5181. Which 2-B schematic?

Dean -

Yes, each schematic has a 'serial number'. The three schematics are

420612001 - 4/20/61, for s/n 2001 to 4499.

124614500 - 12/4/61, for s/n 4500 to 6289.

531626290 - 5/31/62, for s/n 6290 and up.

Clean _clear_ scans of all three versions are on my CD for the 2-B, plus
a 'Revised and corrected' version of 420612001.

Welcome Fred
It was on an old "official looking" Drake radio site but can't find that one anymore.
Having used lots of #1613 I can personally add if it isn't perfect it is very close.
Krylon has changed marketing to now label things by name rather than number although a few specialty internet stores still come up with #1613
The others cross it to Krylon Satin Black
I can't tell a difference and I'm a bit of a critic
You make it spatter on the final coat by enlarging the spray hole

Thanks again, Paul. I'll give it a try a bit later this year. Right now I'm doing some Heathkit restoration and have come across a pretty incredible tool in the paint department. It may be common knowledge, I don't know, but there is a company called Preval that makes an aerosol spray system that can atomize and fine-spray virtually anything, but especially paint of your flavor choice! The system is available online, but may also be found at the local Sherwin Williams paint store and is dirt cheap (as in less than $10)! Using high-grade, computer color matched acrylics, I have just sprayed an SB-102, HW-100 and SB-600. The results are beautiful. This opens up a whole new realm of possibilities for me!

From: ctrpoint2004
Topic: 5188 Message: 5188

Greetings to all group members and readers. Downsizing a bit around the shack and have for sale the first of the legendary Drake Twins. Both receiver and transmitter in very good condition. Virtually perfect front panels. Slight scuff on top rear of transmitter cabinet, not really noticable. Exteriors on both about an 8.5. Very little copper corosion on chassis. Both units serviced and tweaked by Gary Poland, W8PU. Original manual for the R-4 (the one that actually came with the receiver) and printed copy of T-4x manual. No AC-4. See listings at Drake Virtual Museum for specs on units and my Photobucket page for pix of these.

Receiver $275, Transmitter $225,
both together $475 plus shipping.

From: Ken Simpson, W8EK
Topic: 1764 Message: 5189

Drake items for sale:

Case for Drake TR-33 C
This is the black case that fits the Drake TR-33 C, and has
cutouts in the back for antenna, power, etc. It includes
the shoulder strap, and is in good shape. $12

Case for Drake TR-22
As above, but for the TR-22. No shoulder strap. $10

3 pin mic plug for TR-22
This is the small 3 pin mic plug that fits the Drake TR-22
mic jack. It is much smaller than most of the mic connectors.
This one has been used, but should still be usable some more. $10

Dual Meter SWR Bridge:

Quement SWB-2

This unit features two separate meters -- one for reading
forward power and another for reading SWR. This permits one
to easily monitor both the power going out, and the SWR on
the antenna at the same time. They were made in Japan, and
labeled with various names, including Swan, Siltronix, and
Quement. SO-239 connectors on each end.

It will work on HF, and VHF, covering 3 to 150 MHz, so is
ideal for the new rigs that include 6 and 2 meters.

It works fine and looks great. With paper work for $40.

SWR Bridge / Field Strength Meter:

Royce 2-100 Single Meter SWR Bridge / Field Strength Meter

With SO-239 connectors, it covers from 3 to 150 MHz,
covering HF, 6 meters, and 2 meters, so is ideal for the new
rigs with 6 meters and 2 meters in them.

This one works fine, and looks extremely nice. I do not see
any scratches on it, but it does have a previous owners name
on it. In its original box with original instructions. $32

Prices do not include shipping from Florida.

Thanks.

73,

Ken, W8EK

From: Bry Carling
Topic: 5190 Message: 5190

REDUCED: MIlitary Sirplus VHF power amplifier
VHF Linear Amplifier, 50 - 100 MHz, AM-1180/GRC

This military surplus workhorse was designed to cover 50-100 MHz, and the power level is officially 250 Watts max input. Great for 6 meter DX. It was originally
used with the T-302/PRC transmitter. Complete with 4X150A tube and everything
needed. Excellent condition, Easily modified to run more power with a 4CX250B
tube as W4DEX and others have done. Simple, basic workhorse amplifier. Easy to
get at everything internally and not a huge size. Needs power supply of approx:
1250V DC at 200 mA, and 6V AC at 2.5 A. You could sSimply add a regulated
screen supply for all-mode linear amplifier operation. Uses N connectors for RF in
and RF out. Dimensions: 12" X 6.25" X 13.5" deep.

Was $115.00

Now available for $75.00 plus shipping

Picture and details at:

http://www.af4k.com/radios.htm

73 and thanks for looking at this electronic marvel!

5191. Curious about TR4 "#12 Lamp Fuse"

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-04-10 11:46:05 UTC
From: w7jze
Topic: 5191 Message: 5191

So tonight I was setting up a second station next to my ole' trusty Drake TR4 station. Both stations are on 7.114. Both stations are directly connected to separate ANTs in my backyard. I'm a CW OP and as I was tuning the other station (YIKES, a Swan 500c, don't tell :-) I noticed a BRIGHT LIGHT shinning out of the back of the Drake TR4. Now THAT can't be right. I looked into the Drake as I keyed down the other station one more time to see where the light was coming from and I see a LIGHT BULB shinning inside the Drake as I keyed the other station. Lots of RF floating around my small backyard and both, separate ANTs are pretty close to each other.

I dragged out the Drake TR4 schematic and I see a "#12 Lamp Fuse" in series with the ANT on J4. I "suspect" that it is there to keep the RCVR circuitry front end from over loading so much that damage cannot occur (is that even possible?).

I further suspect that Drake used a LIGHT BULB as a fuse to give a visible indication to the OP (like me) that HEY DINGBAT, BACK OFF ON THE RF WITH THE RCVR ON :-)

I had previously turned the RF gain and the AF gain all the way down on the Drake before starting to tune the other station, but the light was on BRIGHT regardless of AF / RF gain settings (as it should be when reviewing the schematic). When I DISCONNECTED the Drake's ANT the "#12 Lamp Fuse" light bulb stopped shining when the other station was key down.

QUESTION: Would someone please confirm that my suspicion about the #12 Lamp fuse is correct (visual indication to the OP of excessive RF into TR4 RCVR circuitry).

NOTE: I did not see such a light coming out of the SWAN rig when the DRAKE was keyed, and checking the 500c schematic, I see no fuse in the ANT line, light bulb type or other. I wounder why DRAKE has such a device and SWAN didn't???

Thanks in advance for any help in scratching this BRIGHT LIGHT curiosty itch.

Bill -

Yeah, you're right, it's NOT good! :-)

I think the bulb was included in the TR series because they were designed for mobile use. Of course in mobile operation it's quite possible to pull up next to another ham, say at a hamfest, - or - one of the trucker CB'ers that run a KW! So very high level RF is a definite possibility. The ANT input goes to a small several turn link on T9, and I have seen them 'charred' from too much RF, (or nearby lightning strikes,) but always with a piece of wire or other short across the bulb circuit! Someone too lazy to find a proper #12 bulb, or even solder pigtails onto a #47 bulb which has the same electrical specifications. Then you have a REAL problem as a T9 is no picnic to replace, assuming you can find one now.

I must admit I've never actually seen a bulb glow though!! A bulb is a pretty good 'fuse', plus it also has a very low resistance when cold, that increases with temperature. I suspect this is why a bulb was used, rather than as a visual warning! Also, the bulb isn't intended to blow out, disabling the radio, but just to limit the amount of RF allowed into that poor little link........

Anyway, this is one reason why antenna switches ground all unused positions.! I would suggest that you disconnect the antenna from the radio not being used, as I'm sure the Swan has a limit as to how much RF can be absorbed without damage, and no bulb to protect it. The most convenient arrangement would be two coaxial antenna switches connected 'back-to-back' so that one could select the radio and the other select the antenna. Certainly there are other switching or patch panel options too.

I've seen this idea elsewhere. Bose had problems in the late 1970s with users blowing tweeters in their 301 bookshelf speakers, so they began sending out a kit with a "fuse lamp" and socket with each replacement tweeter. The first time I saw one, I immediately recognised what it was - a standard automotive dome light lamp! It worked, we never had one come back after the lamp was installed.

Polyfuses behave in a similar manner, but I suspect they wouldn't work well at RF.

Your fuse trivia for the day....

AHhhhhh... Now ^^ THAT ^^ makes sense!

> I must admit I've never actually seen a bulb glow though!!

:-) Me neither!! :-) And it man-o-man it was BRIGHT!! It lit up the
wall behind the Drake with a screen pattern of dots as the light
streamed through the perforated back panel. Bright like a 5 D CELL
flashlight. I suspect that not too many more RF watts would have made it
dark... permanently :-)

Thank you so much for the answer and the sensible recommendation. Yup,
I'll get a proper ANT switch that grounds the unused connections.

VRY 73 and TNX AGN!

Hi Jim,

Clever little (simple) LAMP circuit that seems to have many applications beyond RF limiting. I haven't heard about POLYFUSES before, but I bet they don't light up as BRIGHT as that lil' #12 LAMP in the back of the Drake :-)

PS: I used to sell PCBs to Bose in their BEAUTIFUL downtown San Francisco location in the early 90's. My memory fades as to the engineer's names that I worked with, but "JIM" sounds familiar. "General Circuits" was the vendor (long gone now). Sound familiar to you?

Thanks a lot for your reply!

Some Collins receivers had a neon bulb in them to protect the antenna input. It was not in series but from the antenna to ground and designed to fire if the RF level exceeded a certain point. Any builder who was involved with supplying the military or dept of state with radio gear in the 50s through the 70s had some sort of circuit.

In the older stuff they suggested a set of contacts on an external relay, which would also mute the receiver, that would open when the transmit switch was closed or was operable when another station was on the air with high power; thereby isolating the receiver input circuits. Most of the antenna input coils links were of wire that would carry milliampers so the design was critical in high power situations.

AHhhhhh... Now ^^ THAT ^^ makes sense!

> I must admit I've never actually seen a bulb glow though!!

:-) Me neither!! :-) And it man-o-man it was BRIGHT!! It lit up the wall behind the Drake with a screen pattern of dots as the light streamed through the perforated back panel. Bright like a 5 D CELL flashlight. I suspect that not too many more RF watts would have made it dark... permanently :-)

Thank you so much for the answer and the sensible recommendation. Yup, I'll get a proper ANT switch that grounds the unused connections.

VRY 73 and TNX AGN!

Bob -

There are two filters in a TR-4. You need to specify which one?

Thanks Garry.

The filter is for the USB side of the rig. Designated 9.0-2.1/8/U. It is part of the unit marked A1870-A1.

Any help would be very much appreciatred.

Bob
I am working on a bad 'L' filter for a TR-4. I am going to try and repair the one in the radio. It is an 'L' filter.

If you want a new replacement try InRad they sell em...

For pix of my filter with the top off. http://pgerhardt.blogspot.com

I have two sets of crystals on order, a matched to 30 Hz set for each filter. Not sure if I can get it to work again but it will be interesting.

Garey
Thanks for the link! Will be helpful I am sure. I did find a source of matched crystals for a reasonable price. I bought 3 sets and will have to test them when they arrive.
One set is 9.0015 and 2 are for 8.9985. It will be interesting to see how this project goes.

Getting the can open was a bit of a trick and only 3 of the original xtals survived. Probably at least one was bad but could have been more. Fuse lamp was bad too and couple of other issues too. It is coming along and is always a learning experience here.

Purchase only Sylvania, Zenith, RCA or other NOS USA tubes. There is not a sub but I believe a 6ge5 will work if you only use the Drake on bands below 20 meters. Not sure of the actual number of the tube however, I'm sure others will help.

5206. TR-4C: Can't adj. PS bias

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-04-15 02:26:50 UTC
From: fdonnelly98
Topic: 5206 Message: 5206

Hi all. Just ran into a problem with my TR-4C. I can't get the power supply bias any lower than 0.25. (manual says 0.1)
I had packed it away 2 months ago and I was able to adjust the bias to the recommended 0.1 before I packed it up to relocate my shack.

My question is, would you suspect the PS or the TR-4C. Is the bias adj being high rather than low critical. I know that no or low bias can destroy the finals.

I have the power supply rebuild kit and I intend to make the conversion. Do you think it is the Power supply.

Just checking before I dig into it. Love the group. Many good topics.
Many thanks in advance Frank KI0RQ

Frank -

Most likely the power supply. The BIAS supply should put out about 40 -
80 VDC, and you should get 0.1 A at about -65V.

Do NOT run the transceiver with 0.25A even for a short while as that
overloads the PA tubes.

The rebuild kit is a great idea!!!

Hi Garey;
When I saw the high bias I shut it off.. I plan on shorting out pins 1 and 2 on the AC-4 and check the - voltage on pin 9. that should be the bias voltage.I went to the file section and found a good description of the connector plug.
Being that I was planning on rebuilding the AC-4, I was hoping I didn't have another problem with the TR-4C. It worked great before packing it up. I am not really very familiar with the Drake line rigs.
Many thanks for your response

Hi again Garey; just fired up the PS and the trusty old 410C and
found that the full range of the bias adjustment only gives me
-22V to -52v. cant get to that -65v. So time to update the PS.
hope I didn't hurt the finals. I do have a NOS matched set, just in case I need them. then
I would have to check the neutralization& driver bias.
I will give you a shout when I finish the AC-4 rebuild.

Hi All:
Doing alittle spring cleaning, and am selling one of my Drake stations I have a really nice TR4 with the MS4 speaker and AC4 power supply with D104 silver Eagle Mic with the correct Drake plug.
The power supply was rebuilt by a well known Drake tech, and the TR4 was aligned also by him.
The units are in excellent physical and electrical condition. I am asking $620.00 shipped in CONUS.
Thank you for looking
Wayne

Hi All:
Maybe three times is a charm, I am relisting my TR4 station again at a lower price, I really need to sell it as I have no room for it as we will be moving to a smaller place, here we go:
 I have a TR4 with the MS4, AC4, and a D-104 Silver Eagle Desk mic. with the appropriate Drake plug.
All units are in excellent physical and electrical condition, the TR4 was aligned by a well known Drake tech and the AC4 was completely rebuilt by the same Drake tech.
It comes from a non smoking environment and I will provide pics upon request.
I am asking $475.00 shipped in Conus.
Thank you for looking
Wayne

If they are not sylvania's or GE's you may have to go through neutralization. In some cases, the GE and Sylvania tubes are simply rebranded to that vendor. The RCA's are another brand/manufacture. I never had to neutralize a new set of Sylvania's. Never used a GE, but some bad stories on RCA's. Eventually the RCA's will work, but took some time and effort. Most problems are above 20m, and mostly on 10m. The 3 tube transcievers were more difficult. All tubes should be matched within 5% or better.

Most all US tubes will work. But Drake only sold Sylvania's up to near the end. Then I think they did try subbing other available brands, but then ran into service issues with the replacement tubes. I think in the end they sold GE's, but not sure....memory fades on that part.

Theres a ton of information out there on Drake TR tubes. www.wb4hfn.com has lots of info, as does the Drake Museum site.

I just bought a Drake R-4B and MS-4 speaker off of Craigslist. It's in perfect condition and has 10 optional crystals installed. All I can say about this receiver's frequency stability and audio quality is WOW! I have bought and sold countless receivers over my long life, but this one blew me away.

Great find. I got a pristine SPR-4 from Craigslist. And it was only 10 miles away!
I sold my C line when the third baby was born. He is 31 now and I have the B line and love it. Although most of the time I use a TR-3 with RV-3.
You really can’t kill these old rigs.

5223. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-04-17 19:39:13 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5223

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

It's pretty hard to beat the quality of the product provided by Tom at HayseedHamfest.com

What really surprised me was the speed of delivery on a custom multi-section cap for the Drake 1A, a cap he does not normally stock. That cap was not only the same size and value as the original, but it was polished from solid copper tubing to better match the copper chassis. Based on what he did for the 1A, I suspect he could build any multi-section cap for old boatanchors and vintage Hi-Fi gear.

I have used Toms in a Drake 2B. It was not has difficult as I thought to remove the solder tabs. I did it with a medium sized pencil iron even.

Put a couple of new 2B pix on the blog and you can see the new Can. An older post shows a few close ups. I just put a bunch of new caps in the R4B but have not yet done the Can, when I do I will go to Tom at Hayseed again. If I am going to go to the trouble of pulling the can it would be nice to have it look nice.

Pix of a Hayseed Hamfest can on a 2B and some R4B and TR-4 pix as well

From: Wayne Skiba
Topic: 5235 Message: 5235

Hi All:
I went to tune up my TR4 on 80 meters with a dummy load and I set the bias as per the manual, and everything was fine, I started the procedure to tune up on 80 meters with the dummy load I moved the function switch to the X-CW position and so far so good, and the plate amps were moving up the scale slightly, and when I went to peak the rf tune control for maxium plate current, the needle was pinned against the other side of the meter and a loud whistling came from the speaker, and then just darkness.
I checked the fuse in the ac4 and found that it had blown, I had put another 5 amp 250volt fuse in and I seen a bright light under the power amplifier cage and the second fuse blew, and I smelled like something was burnt. I unplugged the power supply and took off the botton cover and noticed that a small 1/2 resistor was seared under the power amplifier cage. I put the bottom cover back on and put in another fuse and turned the tr4 on again and noticed a bright light coming from the bottom of the p/a cage again and I decided to shut her down and ask for help.
So please let me know how to fix this problem as now I am afraid to turn the tr4 on even just to listen, as it seems to keep blowing fusues and a strange light comes on under the pa cage just before the fuse blows.
Thank you
Wayne

Wayne -

You've probably destroyed your finals by replacing the fuse repeatedly. One of more are probably shorted, destroying the Cathode resistors under each socket.

The initial problem was failure of the BIAS supply in the AC-4. I suggest (for the second time today,) the 'theheathkitshop.com' AC-4R rebuild kit.

Aside from new finals in the transceiver, you'll probably need to replace the 15 ohm, 1W Cathode resistors under each socket, and quite possibly the meter shunt resistor as well. Hopefully the Cathode RF choke and the Plate RF choke have survived.

Lesson 1: Don't ever just replace a blown fuse with another without determining what caused the first one to blow. Yes, you might 'waste' some time troubleshooting, only to discover that the fuse just died from old age, but that's better than what you have now.

Lesson 1a: Those of you who are tempting fate with original BIAS supply electrolytics need to recall the computer hard drive mantra. "It's not a question of _IF_ it will fail, only _WHEN........_!" With finals $30 and up EACH, (not to mention 'collateral' damage,) an AC-4R kit is well worth while.

Garey,
You bring up a REALLY good point that bears repeating occasionally. These old rigs are NOT plug and play, they WILL need some care and feeding. It is great that we are cultivating a new crop of enthusiasts, but they didn't go through the times we did when these were fairly new rigs. Even then, they needed maintenance often, in my experience. Of course, I was running them HARD on RTTY, but I went through some cathode resistors and other sundry parts, hi. Now they need some fairly major surgery to make them resonably reliable.

One question, what is your recommendation when we need to replace the cathode resistors and other carbon composition resistors in these rigs. My old stash of 15 ohm resistors have drifted up. I realize that I bought them in the mid 1970's from my favorite surplus store, so they are OLD, and it's time. I need to replace the ones in my rigs as I go through them and am confused by the "new" nomenclature of ceramic and such resistors. I'd like to do it once and use them for a few years, hi. I also have some needed in my "Brand X" 30L1 amp that I need to replace (10 ohm 1 or 2 watt in the HV supply) and the cathode resistors.
73,
Don, WB5HAK

Gary:
Thank you for the information, the guy I bought this station from told me that the ac4 was completly rebuilt by Jeff Covelli in 2008, as a matter of fact there is a sticky note on the back of the ac4 that says new ac4 boards on 06/16/08, and the TR4 was aligned.
 He also said that he did not use it much as it was sitting on a shelf with the ms4,ac4 and the D104 Silver Eagle mic. for the past two years.
From that info I really did not expect any trouble? I just thought that I accidently over drove the finals and they drew too much current and I blew the 5 amp fuse.
Well maybe I have to go back to the drawing board.
Thank you
Wayne

Don,

I usually replace old carbon comp resistors with new carbon comp resistors. Call me a purist but I like to keep things as original as possible. I did just that with a Galaxy GT-550 and GT-550A where the 1W, 2W and some 1/2W carbon comp resistors were reading high. Mouser sells them (Ohmite) as does Just Radios and other distributors.

Best Regards,

Subject: Re: [DrakeRadio] AC4 Power Supplies, Electrolytics, Resistors, Etc.

Garey,
You bring up a REALLY good point that bears repeating occasionally. These old rigs are NOT plug and play, they WILL need some care and feeding. It is great that we are cultivating a new crop of enthusiasts, but they didn't go through the times we did when these were fairly new rigs. Even then, they needed maintenance often, in my experience. Of course, I was running them HARD on RTTY, but I went through some cathode resistors and other sundry parts, hi. Now they need some fairly major surgery to make them resonably reliable.

One question, what is your recommendation when we need to replace the cathode resistors and other carbon composition resistors in these rigs. My old stash of 15 ohm resistors have drifted up. I realize that I bought them in the mid 1970's from my favorite surplus store, so they are OLD, and it's time. I need to replace the ones in my rigs as I go through them and am confused by the "new" nomenclature of ceramic and such resistors. I'd like to do it once and use them for a few years, hi. I also have some needed in my "Brand X" 30L1 amp that I need to replace (10 ohm 1 or 2 watt in the HV supply) and the cathode resistors.
73,
Don, WB5HAK

Hi Don -

Yeah, I beat mine up on autostart rtty too.... I had three pairs that ran 24/7 based around 14.075
MHz. Each transmitter had a fan on the back of the PA cage, and they would often run 30 minutes or
more at full power. Of course finals were about $3 each... :-)

I like to use the ceramic composition resistors from Ohmite. Their OX and OY series are about as
close as we can come to non-inductive, carbon comp resistors today. You don't want carbon or metal
film as they don't handle surge current very well. I have heard rumblings of resistors burning up,
either wirewound or metal film, but I suspect metal films were the culprits.

OH by the way, the ONLY 'failure' I had in about five-six years of this kind of service was an open
filament on a 12BY7.

Gary:
Thank you for the information, the guy I bought this station
from told me that the ac4 was completly rebuilt by Jeff
Covelli in 2008, as a matter of fact there is a sticky note
on the back of the ac4 that says new ac4 boards on 06/16/08,
and the TR4 was aligned.
He also said that he did not use it much as it was sitting
on a shelf with the ms4,ac4 and the D104 Silver Eagle mic.
for the past two years.
From that info I really did not expect any trouble? I just
thought that I accidently over drove the finals and they
drew too much current and I blew the 5 amp fuse.
Well maybe I have to go back to the drawing board.
Thank you
Wayne

It would be interesting to see what failed. If the bias
supply failed it should be obvious when measuring the
voltage with the supply disconnected from the transmitter.
Then the question is what causedit to fail. Its a very
simple supply. The filter caps are the most obvious suspects
but it could be anyhing else in the circuit. I should point
out that the rebuilding kit does not change the origina
circuit, it only replaces the caps and rectifier. Real
protection would need something more sophisticated such as a
crowbar that would shut down the HV if the bias dropped too
much. Loss of bias in any circuit will kill it.

Wayne -

OK, that's more information. I'd be willing to bet that it was loss of
BIAS that caused your problem. Having the PLATE meter suddenly soar and
peg is classic BIAS loss.

You can run the AC-4 without the transceiver by shorting Pins 1 and 2 of
the Jones connector. Carefully, as it will have 120 VAC on any jumper,
plus the 300 and 700 VDC busses are HOT.

You should get about 750 VDC, 300 VDC and ~50 - 100 VDC negative
variable with no loads. There's an article at

<http://www.wb4hfn.com/DRAKE/DrakeArticles/TechTips/PowerSupplyTroubleshooting.htm>

I'd check the components in the PA cage under the chassis, it's possible
that the overcurrent developed a shorted turn in the CATHODE RFC, smoked
one or more 15 ohm Cathode resistors, or ... With 'flashing lights'
under there it shouldn't be hard to find 'what' blew!

I looked at a lot of places. I also bought some so called NOS off of Ebay with mixed results. I even bought some NOS Allen Bradley resistors from Surplus Sales of NE but they were reading high. I complained and they replaced them with ones that were within tolerance (I'm glad they measured them prior to shipping). Antique Electronic Supply has them as well but has limited selection of values and wattage.

> Don, WB5HAK

I've found that the drift of carbon composition resistors seems to depend a lot on the make and value. The cathode resistors in my T-4XB were of two different types, one had a seamless case, I think probaby Ohmite, the other had a seam around the long way. The seamless one was within specs, the one with the seam was very far off, maybe 50% or more. I've also found that very high value resistors tend to drift more than low value ones and do NOT always drift up. Heat seems to be the enemy; resistors subject to a lot of heat, either internal or extermal, seem to drift a lot. Also, low power rating drifts more than higher rating, that is, you will find more 1/4 or 1/2 watt resistors off than 2

watt providing the 2 watt ones have not been dissipating close to their limit.
The element of carbon composition resistors is made of a mixture of carbon particles in an insulating carrier. Evidently, as they are heated, or perhaps even just with time, some of the contacts between the carbon particles become poor so the resistance goes up. In some types the head of soldering is enough to move the resistor beyond its tolerance. Not all brands were made the same way and not all are the same in ageing or resistance to the effects of heat. Back when carbon comp reistors were the mainstay of the industry the ones with the best reputation were Ohmite and Allen-Bradley molded ones.
Film resistors, which do not have an intermediate insulater, do not suffer from this effect, both carbon film and metallic film resistors are very stable and most will take tremendous power overload without changing value. Composition resistors have two virtues: one is that they do not go open unless seriously overloaded (burned out) and the other is that high resistance values can be made with low residual reactance. The main source of failure of film and wire wound resistors is at the connection of the terminals to the resistance element. There are a couple of different ways of connecting, probably the most reliable are properly made conductive plastic (epoxy) at the ends. End caps unless swaged perfectly can develop oxidation which will cause them to go open. The same with the welded terminations of wire wound resistors, the welds can oxidize causing the resistor to go open. Unless either type is absolutely fried the element termination is the usual cause of failure.

I would never use old NOS carbon resistors when replacing those in a Drake. The OX and OY resistors from Ohmite work great, are new, are inexpensive and are “right on” the resistance value specification . They are usually matched in value too with better tolerance specs.

Don
Metal oxide is the sensible replacement.
Any old carbon comp reistor probably isn't close to the value it should be anyway. Any new carbon comp resistor is EXPENSIVE. I avoid both.
Metal oxide are rated for RF service and to get one close to the same physical size as the old carbon comp you will be up grading your wattage too.
Carbon film are also ok to use. I just think the metal oxide are a bit heavier duty.
Do not use metal film unless that is what is being replaced.
IMHO

Back at the resistor factory where I wasted part of my youth we made carbon and metal film resistors exclusively. The carbon film units were mil spec and the metal film were established reliablity having to meet much tighter than mil spec (most went to NASA contractors). All were given a seven times overload test before being adjusted to final value. A bad batch sounded like Chinese firecrackers but the survivors would take it. That is seven times rated power for perhaps thirty seconds.

Very high value, low power, film resistors may have
rather thin coatings and long spirals to obtain the high
resistance. They will have some inductance and may have
enough voltage between the "windings" to arc there but the
voltage would have to be very high. I've measured some
medium value (1 to 20K ohm) half watt carbon film resistors
on a Boonton RX meter and found them to be relatively
non-reactive. I can recheck this to be sure. The RX meter is
an ideal instrument for making this measurement.

For one, you can look at the board and if it came from The Heathkit Shop it will have his company name and lettering printed in white, on the board. That still does not tell you if it has parts on it from The Heathkit Shop. But, if it is not his board, you know none of it came from him. Go to The Heathkit Shop web page: http://www.theheathkitshop.com/ Here you will find pictures of his board. Does yours look like it came from him?

Lee, w0vt

Lee:
Good question, I don't know, Jeff Covelli did the work on the tr4 and his note was that he replaced ac4 boards with a dte of 06/16/08.

Who made the replacement AC-4 boards? The Heathkit Shop calls his AC-4R boards. Then too, The Heathkit Shop sells the plain board without parts or a board with all the parts. Even if it was a Heathkit Shop board, did the refurbisher install his own parts which could have been inferior?

From: Paul Kraemer
Topic: 5254 Message: 5254

Not the TR-4 expert here, just sharing my weekend
experiences with a recently acquired TR4-C
It came from a very good home and had been thoroughly maintained by the
original owner.
I got it a part of a complete station and I didn't even intend to keep it,
just wanted the other Drake gear.
I thought before I sold it I at least wanted to check it out.
I used it a couple hours on a few weekiends and it was fantastic except the
power connector to the AC-4 seemed a little iffy. I had to wiggle it a bit
to get the thing to play.
One evening I turned it on and turned my back for an instant. The TR4-C
keyed up, probably mic sitting too close to the speaker tripped the vox.
Problem is it didn't un-key, ran the finals a few seconds at full current
and destroyed them.
Long story (trying to be brief) is that aparrently TR-4 and T4X can and will
key
accidentally or on purpose and if the bias fails for any reason you have
3-mile island event in the rig because the failed bias will prevent the
relay from opening and will off course also destroy the 6JB6
All that ended up that contributed to this fiasco is the power plug pins on
both the TR4-C and mating cable were "sticky" with some film or oxidation
and the bias voltage fell off from the -40 or so it should be.
Since I was now into the radio I deceided to thoroughly check everything
including the already mentioned resistors and electrolytics. Everything was
fine. I have the equipment to measure about any aspect of a component I
desire. The electrolytics test better than new. The cathode resistors were
not fried. They were adequate wattage to
withstand the current. Posiibly in early designs they were not but mine was
a late
build. Maybe someone already replaced them but if they did they were very
good solderers.
Moral---it is the little demons in life that cause the biggest problems.
The TR4-C is playing fine now, with an old mis matched set of finals
(another no no) and all it took was cleaning a connector!
I learned a lot about TR-4's along the way. I love Drake gear, mostly the
receivers, and have had one or the otherof them since the early 60's. The
transmitter problem I experienced is IMHO just poor design. I am an
industrial control designer by profession and that just type behavior won't
cut it there.
Just my sharing an experience
Paul K0UYA
PS I'll replce the 6JB6's as soon as they arrive but keep the used ones for
troubleshooting.

No problem with Ohmite OX and OY. They are a ceramic carbon resistor and are VERY stable. Much better then old type carbon resistors. They are today's standard in industry when you want a low inductance resistor. Put them in your Drake and they will outlive you! That is, unless your fry and overload them.

FWIW - I've been purchasing Ohmite OD/OF series carbon composition resistors (1/4w, 1/2w respectively) through Mouser. However, pricing is a bit steep. About 50-cents ea. for either 1/4w or 1/2w, and [gulp] about $2 ea. for 1-watt. At these prices, it makes sense to use them only where needed and not throughout an entire project.

http://www.ohmite.com/catalog/pdf/little_demon.pdf

In my Drake 1A project, I opted for all carbon film for replacements instead of carbon comp. I must have changed out nearly two-dozen resistors that were either moderately out of tolerance, or in the case of the 33K screen resistors, WAY out of tolerance as they drifted upward to 4X their specified value. The Rx sensitivity was poor. I learned the hard way that screen resistor tolerance can be vitally important to a tube receiver's health.

Hi Don -

Yeah, I beat mine up on autostart rtty too.... I had three pairs that ran 24/7 based around 14.075 MHz. Each transmitter had a fan on the back of the PA cage, and they would often run 30 minutes or more at full power. Of course finals were about $3 each... :-)

I like to use the ceramic composition resistors from Ohmite. Their OX and OY series are about as close as we can come to non-inductive, carbon comp resistors today. You don't want carbon or metal film as they don't handle surge current very well. I have heard rumblings of resistors burning up, either wirewound or metal film, but I suspect metal films were the culprits.

OH by the way, the ONLY 'failure' I had in about five-six years of this kind of service was an open filament on a 12BY7.

NOT plug and play, they WILL need some care and feeding. It is great that we are cultivating a new crop of enthusiasts, but they didn't go through the times we did when these were fairly new rigs. Even then, they needed maintenance often, in my experience. Of course, I was running them HARD on RTTY, but I went through some cathode resistors and other sundry parts, hi. Now they need some fairly major surgery to make them resonably reliable.
>
> One question, what is your recommendation when we need to replace the cathode resistors and other carbon composition resistors in these rigs. My old stash of 15 ohm resistors have drifted up. I realize that I bought them in the mid 1970's from my favorite surplus store, so they are OLD, and it's time. I need to replace the ones in my rigs as I go through them and am confused by the "new" nomenclature of ceramic and such resistors. I'd like to do it once and use them for a few years, hi. I also have some needed in my "Brand X" 30L1 amp that I need to replace (10 ohm 1 or 2 watt in the HV supply) and the cathode resistors.

If Jeff did the work, you can count on it being correct. I don't know for certain if he uses the AC-4R 'kit', or buys the boards, or uses another product entirely, but whatever he's done has been done right!

There are several of these going on right now, but a failure that quickly sounds more like a component (bias rectifier?) with a product defect, 'infant mortality' or the old 'bell shaped curve'.

Could be an electrolytic cap, could be a pinched wire, could be a loose Jones connector, etc., etc. Repair plan is to resolve the power supply problem while disconnected from the transceiver, and then resolve the damage to the transceiver (via ohmmeter and visual inspection), and THEN put them together.

Richard -

Engineers that I have worked with recommend that carbon or metal film resistors are great for low power, low noise applications, but that they do not handle surge currents well at all. Certainly no where as well as carbon comp. Failures occur at terminations, the 'weakest link'. Inductance only becomes a consideration at extremely high frequencies and very high resistance values, 10M and up.

Metal oxide films are much better with regard to surge currents, and ceramic comps are better still, only exceeded in this regard by wirewound metal cased.

With these products available, I can't see any reason to use obsolete carbon comp resistors, with their drift and noise problems, aside from physical appearance. The antique guys like to use 'Body-End-Dot' resistors too, but the smart ones put a modern resistor either in or under it! Earlier still, resistors were a piece of paper with a pencil mark on it!! :-)

I think the Ohmite OX / OY ceramic composition resistors are the best option for the Cathode resistors in the T-4X(any) transmitters. A two watt ceramic is a little smaller than a 1W CC, is more accurate initially and over time (best 'matching' of parallel tubes), and will withstand heavy current surges in this type of use.

Topic: 5237 Message: 5261

Highly recommend anyone with a stock AC4, (or ac3 for that matter) to rebuild the power supply as soon as possible. In my case, my AC4 was purchased brand new by me at Dayton in 1979. One of the last made. Even with the high serial number and known easy but regular operating history, the supply is/was still pretty long in the tooth. That's 32 years folks !! I rebuilt the AC4 along with my L4ps at the same time. I've never regretted the expense, since I have a fairly minty TR4C/RV4C investment to protect, and... who wants to buy new 3-500's if you can prevent it !!??.

If you also go through your transceiver, receiver, transmitters and look for any and all electrolytics, I also suggest its time to replace them as well. Check the cathode and plate resistors too. Its very easy for those to get out of spec after 30-40 years of use. Check all grounds, clean corrosion around any ground tabs.

All those things are necessary to enjoy your radios for years to come. There's a lot of info available on the web to help anyone wanting to refurb their radios. www.wb4hfn.com is a good resource, just click on the "drake" tab. Also google up the Drake Museum site. And, you can always visit the many help groups like this one.

Complete power supply board kits can be had from the "heathkit shop" as well as transformers, boards, soft start, soft key and other parts from "harbach electronics" on the web.

Wayne -

I assume you mean a 68 ohm resistor in the PA cage under the chassis. That's a Screen decoupling resistor. It _MAY_ indicate that a tube developed an internal short, a 'flashover' that cleared itself. In any event, it's possible that one tube is pulling less than it's 1/3 share of the total plate current, thereby overloading the other two. It would be a good idea to measure the Cathode voltage across each of the 15 ohm resistors to verify that each has about the same voltage across it.

Glad that there were no more difficult to replace components damaged.

Is this the same one that you were trying to sell this past weekend?
I would check the finals like Garey had mentioned. One has to be working harder than the other one.

Did you try USB on 20 or 15m? How is the output via a power meter? Try getting a signal report and sound quality check as well. The receiving station may hear ripple, etc...
Let us know.

Brethren!

Long term listener, First time caller...

I am searching for and looking to buy the LC-2-TR Speech Processor manufactured by DX Engineering (then on East Walnut in Pasadena, CA)for my TR4-CW. This device is suitable, to my understanding, for the TR-3 & TR-4C series.

All comments welcome.

Reagrds to all,

Peter

Hi Everyone:
I have reduced the price on my TR4 station to $425.00 shipped in CONUS, it includes the TR4, MS4 and AC4 with the D-104 desk mike all in excellent condition. Pictures providied upon request.
Thank you for looking
Wayne

From: Howard Traxler
Topic: 5270 Message: 5270

I have some Drake 4 series transmitters and have been using a D-104 mic for years. I'm thinking of getting a new mic and wondering what impedance I should be looking at. Thinking particularly of the Heil mics.

Thanks, anybody.

Howard, WA9RYF

High impedance is the proper match. Above 10K ohms, Crystal, ceramic or dynamic. the D-104 element is good without the amplifier.

Howard,
I have a Heil Goldline that I got with a Collins S Line (same mic impedance as the old Drakes) with the impedance transformer in the mic. I haven't used it much, so hard to tell if I'll like it, but it sure looks nice, hi. Point is, if you like the Heil line, they do sell a transformer to be used with them to transform them to high impedance and should be fine. Heil microphones DO emphasize the low portion of the audio spectrum, so you may get reports that you have "too many lows" in your signal, I am not sure about that. On my "modern" rigs, I always cut the lows to get people to like the audio. Just some thoughts. The D-104's are nice, when working, but the elements are near unobtanium, and the replacements from Mouser (Kobitone) don't work well for all. Hope that helps, Howard.
73,
Don, WB5HAK

I'm looking for a good condition "flat" R4B or T4XB dial. The R4B I just received has a warped plastic dial I would like to replace. If anyone has ever flattened a warped dial, how did you do it?

I do not know if this will work or not but you can put the dial in the sunlight between two sheets of glass that are flat. It would be a cheap try before making a new dial which should be doable if you have the right materials to do it.

Ron and Paul,

Thanks for your suggestions. I thought of heat and heavy flat surface with the dial sandwiched in between. I'll give the sun a try. It shouldn't take much to make it flat. Unfortunately the sun isn't out and won't be for at least a week. We have rain and T'Storms for the next week. I'm not in a hurry since the dial does rotate okay but I would like it to be flat.

HI Don,

Yes the address is okay. Thank you very much Don, I really appreciate it.

We just had lightning strike the 150 foot tall 60KV power pole about 300 feet from the house. What a "BANG"!! This happens all the time with severe T'storms. The coax feed line had long since been thrown out into the yard and the rigs switched to the dummy load.

Wow, glad you are okay, Mike, but send some of that rain over here to the Duncan/Lawton area, PLEASE!!!!!! We are having wild fires around here like crazy, already burned many thousands of acres out here. It's so bad, I'm not hearing much artillery fire from Ft. Sill this spring, just the minimum to graduate the guys. So far I am lucky, but not sure how long that can hold. Try to straighten out the bend in that dial you have with mild heat some time. Someone else will have the same problem, and their's might be worse. This is the LAST one of these I have seen or heard of.

The D-104 is BEST without the amplifier. Even better with a 470K or higher resistor in series with the element.

Suggest you will not be satisfied with most any heil dynamic mic with a Drake tube radio. The rigs "like" a mic with about 50k impedance or better, up to say 100k. It takes a minimum of 10k to get the rig going, so to speak. Definitely needs a higher impedance mic to work well. Mics like the Shure 444 (d) set to high or the EV 664 or the D-104 NON-Amplified mics work great. The D-104 works even better with a resistor in series with the mic line to soften the audio a bit. A D-104 with the preamp, should be avoided. Its use can lead to problems with the agc circuit.

I use a EV 664d wired to high impedance with my TR4C, with exc. results. Gain set at about 10 oclock. Same setting for a D-104 or 444 (approximately). Use that for reference.

Heil mic's, in general, are not very high output mics. They work great with Yaesu's and Kenwoods, and you need the IC series with most Icoms. If you do use a heil, and get the little transformer, you'll need to up the gain on the rig considerably to use it. And, your results may not be as favorable as the marketing leads you to believe. Yes, they sure look good. If you want to experiment, I'd buy a used one, wire it up and see if it works for your voice. If you want a transformer, email me off list and I can send you one that is excess to my needs.

Just keep in mind, Bob Heil did not design his mic line for these older tube rigs. He tried to hit the mainstream ham market, with Yaesu and Kenwood being the main focus.

Good luck,
David

You mean "Vinyl" records? Yes I remember those well since I grew up before 8 track and cassette players were a gleam in the engineer's head!

Everyone listened to "AM" radio and music albums was sold on 33 1/3 rpm Vinyl records and the individual hits were sold on 45s!

Most stereo systems were large pieces of "furniture" with lift top lids. My parents bought a Sears AM (mono) and FM stereo system which included a 33 1/3, 45, and 78 speed turn table. "78 speed", who listens to 78 speed? The old records in the 30s and 40 could be played at 78 speed!

The tuning indicator for the receiver was a "1626" eye tube. The eye closed as the station was tuned properly. That was in the early 60s. We didn't have color television until mid 60s. I remember watching "The Big Picture" and "The Cisco Kid" on Saturday mornings on a 20" Black and White television, all tubes no solid state devices. Those were the days. My mother's favorite program was Bonanza on Sunday evenings and Red Skelton on Tuesday evenings, "Brought to you in Living Color on NBC!"... Red Skelton initially ran on CBS but later changed to NBC.

I use an old non-amplified Turner desk microphone I paid $10 for at a hamfest. I replaced the element with a Mouser 25K crystal element, works very well with my T4XB transmitter. I also use a non-amplified D-104 with the original crystal element with my C-Line.

The D-104 does a nice job with tube rigs. I use a non-amplified D-104 with an Heathkit HW-101 and it does a great job. I tried the amplified D-104 with my 1962 Heathkit Marauder, didn't work and audio reports were, "you sound muffled". Changed to the non-amplified D-104 and reports were very good audio.

Thanks all for your offerrings regarding the mic on the Drake series. I am now using the non-amplified D-104 which I have been using since I had my first Drake back in about 1969. I guess I should probably be a bit more conservative about how I drive it, but most of the time I run the drive all the way up. No one has complained--at least not much. I've never heard me, but I think the D-104 is a bit high pitched and sounds a little harsh. I'd like to try something with a little fuller range to get a more natural sound. Maybe there's some kind of equalizer that can go in line with the mic to make what I'm using sound better.--I like my D-104.

What I'm really looking for is a boom. Using a desk stand gets in the way of my computer keyboard and Braille display. So I need to have the mic on some type of a bar that comes in from the side. I'll keep looking.

Hi Everyone:
I have further reduced my TR4 with MS4,AC4 and D-104 microphone, as we will be moving shortly and I do not have room for this station at my new qth. This station is in excellent physical and electrical condition, the tr4 was aligned by a well known Drake tech and the ac4 was completly rebuilt by the same Drake tech,
I have further reduced the price to $375.00 shipped to CONUS, for the complete station,you will not be disappointed with this station. I can provide pictures upon request.Thank you for looking
Wayne

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

You mean "Vinyl" records? Yes I remember those well since I grew up before 8 track and cassette players were a gleam in the engineer's head!

Everyone listened to "AM" radio and music albums was sold on 33 1/3 rpm Vinyl records and the individual hits were sold on 45s!

Most stereo systems were large pieces of "furniture" with lift top lids. My parents bought a Sears AM (mono) and FM stereo system which included a 33 1/3, 45, and 78 speed turn table. "78 speed", who listens to 78 speed? The old records in the 30s and 40 could be played at 78 speed!

The tuning indicator for the receiver was a "1626" eye tube. The eye closed as the station was tuned properly. That was in the early 60s. We didn't have color television until mid 60s. I remember watching "The Big Picture" and "The Cisco Kid" on Saturday mornings on a 20" Black and White television, all tubes no solid state devices. Those were the days. My mother's favorite program was Bonanza on Sunday evenings and Red Skelton on Tuesday evenings, "Brought to you in Living Color on NBC!"... Red Skelton initially ran on CBS but later changed to NBC.

I was in high school when the Beatles came to America and performed at "Crosly Field" in Cincinnati Ohio! Not many folks remember Crosly Field. Crosly Field Sun Deck seats cost "50 cents", standing room only cost "75 cents", going to the movies cost "25 cents" and a gallon of gas was less than 25 cents, "Fill it with Ethol!!". Gas stations had attendants that checked your oil, washed your windshield, and pumped your gas.

Enough of that. Old? If you call 62 going on 63 being old then okay, I'm an "old fart"...:)

Put a 470K resistor in series with the mic element, that will help. 50K is really low for a D-104, the element likes to look into a really high impedance. You should have plenty of drive left, you cold even go higher than 470K to mellow the sound out even more.

Sounds like you have a bad element in your D104. There isn't much you can do to change the way it sounds other than change mikes or get a ceramic head for the Astatic. I suggest you look for an EV 664 which many people don't recognize as good mics. I have seen them at hamfests for low cost compared to others.

You need a high impedance mic, brand really doesn't matter but I would look at the specs for several before you start buying. One thing that many overlook are both handheld and base mics use by Motorola, GE and RCA on their 2 way equipment in the 70s and 80s. They are good mics but ugly. I have seen people give them away at hamfest.

Subject: Re: [DrakeRadio] Re: T-4X or other, mic impedance

Thanks all for your offerrings regarding the mic on the Drake series. I am now using the non-amplified D-104 which I have been using since I had my first Drake back in about 1969. I guess I should probably be a bit more conservative about how I drive it, but most of the time I run the drive all the way up. No one has complained--at least not much. I've never heard me, but I think the D-104 is a bit high pitched and sounds a little harsh. I'd like to try something with a little fuller range to get a more natural sound. Maybe there's some kind of equalizer that can go in line with the mic to make what I'm using sound better.--I like my D-104.

What I'm really looking for is a boom. Using a desk stand gets in the way of my computer keyboard and Braille display. So I need to have the mic on some type of a bar that comes in from the side. I'll keep looking.

I use an old non-amplified Turner desk microphone I paid $10 for at a hamfest. I replaced the element with a Mouser 25K crystal element, works very well with my T4XB transmitter. I also use a non-amplified D-104 with the original crystal element with my C-Line.

The D-104 does a nice job with tube rigs. I use a non-amplified D-104 with an Heathkit HW-101 and it does a great job. I tried the amplified D-104 with my 1962 Heathkit Marauder, didn't work and audio reports were, "you sound muffled". Changed to the non-amplified D-104 and reports were very good audio.

I wouldn't think that the Shure would sond tinny. You may need to align the carrier oscillator, or possibly you might have a problem in the mic amp section of the radio. The resistor mod only applies to the non-amped D-104 - the mic element likes to see a very high impedance load. The "amplifier" takes care of this, it's really an impedance matching buffer with some gain. The extra gain is not needed, and the amp is an extra failure point that can easily be removed. And you'll save money on batteries. :)

>Sounds like you have a bad element in your D104.

Not necessarily. As has already been mentioned, the unbuffered D-104 cartridge needs a high impedance load. The 50K-ish impedance of the Drakes is really too low, and will roll off the low frequency response. There is plenty of documentation on the internet of this effect. The old-timer's trick that I picked up some years ago about putting a 470K (or higher) resistor in series with the element really works. The cartridge still has plenty of output to drive the radio.

Been there done that. I put a 700K resistor in series with the hot lead in the bottom of the D104 mic and it sounds great on my TR4. It took away the tinny sound. If you have another receiver to monitor your output that is really helpful when selecting or adding the resistor value.

Not necessarily. As has already been mentioned, the unbuffered D-104 cartridge needs a high impedance load. The 50K-ish impedance of the Drakes is really too low, and will roll off the low frequency response. There is plenty of documentation on the internet of this effect. The old-timer's trick that I picked up some years ago about putting a 470K (or higher) resistor in series with the element really works. The cartridge still has plenty of output to drive the radio.

470K will flatten the response of the mic but with it or without, the mic should not sound tinny. Of course all we have is a verbal description and I have not heard it. The one thing a D 104 likes is high input impedance. If you have a flat response audio amp then put a 1-4 meg resistor from the grid of the first amp to ground so the mic sees and can respond to high impedance. You may also want or need to add a small cap in parallel, depending on the amp.

The series resistor simply flatens the audio response reducing the bump in the response curve of the D104 therefore if the element is bad it will sound even worse. So if you have a tinny sound with the resistor in series, then you have a bad ememement given the audio chain is operating correctly.

470K will flatten the response of the mic but with it or
without, the mic should
not sound tinny. Of course all we have is a verbal
description and I have not
heard it. The one thing a D 104 likes is high input
impedance. If you have a
flat response audio amp then put a 1-4 meg resistor from the
grid of the first
amp to ground so the mic sees and can respond to high
impedance. You may also
want or need to add a small cap in parallel, depending on
the amp.

The series resistor simply flatens the audio response
reducing the bump in the
response curve of the D104 therefore if the element is bad
it will sound even
worse. So if you have a tinny sound with the resistor in
series, then you have
a bad ememement given the audio chain is operating correctly.

Jim
W5JO

A D-104 should sound bright but not completely lacking
in bass. I am not sure of the input impedance of a TR-4 but
on my R-4XB it sounds fine.
Too low an impedance will cause the low end to roll off
but should not produce a peak. A strong peak sounds more
like mechanical damage of some sort.
Bad crystal elements loose a lot of output or are just
dead. The two enemies of crystals are fracturing, which can
come from very hard mechanical shocks, mostly a problem with
crystal phonograph pickups, or from excessive electrical
drive, mostly problem wtih crystal record cutters. The other
enemy is moisture. The material of which the crystal is made
is delequescent, that is, it absorbs moisture from the air
and becomes mush. Crystal elements of all sorts are
carefully sealed to prevent entry of moisture but sometimes
the seals fail. Another problem is excessive heat. Above

some point the crystals melt and are no longer active. I don't remember the maximum for Rochelle salt but its not much above 100F.
If you measure a crystal element, whatever its application, with an ohm meter it should measure open. It should look like a capacitance. Any resistance indicates the crystal has begun to deteriorate in some way. Fractured or completely melted crystals, whether by heat or moisture, will also measure open so that isnot by itself meaningful. However, if the crystal does not work and is open its bad. If it works but shows resistance on an ohm meter its also bad.
Its also possible for the sound to be distorted if the diaphragm has becom damaged in some way. Most of these units are sealed but someone could still stick a pencil point through the grille and damage it. People do all sorts of odd things.

My 2¢ worth here. Both of my Drakes, the "B" and the "C" T4-x's really like an Astatic G-Stand, with a 10-D head, more than they do the standard D-104, but they do fairly well with the D-104, too.
I can say this though, adding a Heil Fin, with a Behringer Xenyx sound board, does not give it any better frequency range, than the standard 10-D head does.
Hope this small change info helps a bit.

Do the TR4's have internal relays to handle the connection to the 30L-1 or does it require an external relay?

Thank you all.
Richard, thanks for the mic. lesson regarding the xtals. I didn't know about the moisture absorption proble.
But, I used the Shure 444 and the perceived audio by others was the same as what they had heard on the D-"10-4".

I am going to experiment with various resistors and if that doesn't "pan out", then I'll add a cap in parallel.
I will report back with my results.

I "shure" wish that my TR4 was working.

If you are receiving reports that the Shure sounds no different than the Astatic, then find out why first. Those two mics should sound different. You may have issues in the audio section or misalignment of something.

Once that is fixed then you can play with the mics to get the sound "you" want. Everyone has different tastes in audio. To one person a certain combination may sound good but to another it may not so check your radio with an audio generator then work with the mic. Something sounds fishy.

If the D-104 and/or Shure 444 microphone element(s) is/are found to be bad, a replacement can be obtained from Mouser (25,000 ohms crystal element).

Mouser part number 251M022
Price: $12

I've used this element as a replacement in a Turned non-amplified desk microphone. Works very well with my T4XB.

The TR4CW, as well as the other Drake TR3, TR4, TR4C, and T4<any> line of transceivers and transmitters, have internal "N.O." (Normally Open) internal relay terminals wired to the 12 pin power connector pins "5" and "8" to control external devices such as amplifier relays, antenna change over relays, "ON THE AIR" signs, etc. You can see these relay terminals, for example, on page 5-11 in the TR4CW operator's manual (schematic). The relays are shown in "receive". Placing the TR4CW in transmit cause relay "K1" to energize, shorting pins 5 and 8 together.

Well, I thank you for the compliment. A cap across the mic will roll off the highs but not boost the lows. One of the problems with crystal mics is that the impedance is so high that cable capacitance becomes a problem. Low capacitance cable should be used and the length limited. If the mic has a bad peak in it a cap _might_ help but it won't eliminate the peak, only create dips around it.
It might be useful if someone made MP3's or something of various mics in good condition so people could hear what they are supposed to sound like. Of course one must be sure the mics demonstrated are really working properly. I remember a video tape shown to a bunch of us in an audio club. It was a demonstration of various classic microphones. I have some of them and it was obvious that a few of the ones demonstrated were broken despite sort of working. Shure made a number of good microphones and is still in business so they must be doing something right. I have a couple of their old cardioid mics, a 556 and a 55S. The curves for these are on the web. The design is interesting because it was AFAIK the first cardioid made with a single element, other previous directional mics were a combination of a non-directional element with a bi-directional element. The mic works but there are a lot of parasitic resonators in

it. The highs have a broad peak around 4 khz. What I find interesting is that Shure designed the response curves of their later mics to about duplicate these early ones. They have a good response for voice intelligibility. I think the response of the original mic was just a result of the mechanism but it turned out to be advantageous so they just stuck with it even through they could probably have made perfectly flat mics later.

Greetings,
I have a TR4C. I have noticed that my receive audio gets muffled from time to time. I also noticed that by tapping the radio chasiss or just lightly moving the powersupply cable it clears up. I still have not found a loose ground anywhere. Any ideas on possible culprits?

Hi Dan
I recently got a tr 4c from my friend's estate... it had a similar problem. I carefully cleaned the tube pins and sockets and then located the tube that was acting similar to yours. Once located I took the time to re solder the connections on the tube socket...I did that on many of the tubes as long as I had it apart and...the problem is gone!

Cheers
Mark

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

Hi. In an earlier post I requested some help locating a USB filter for a plain TR4. I recently saw an ad for both filters in Ebay, but, they are for a TR4C.
Does anyone know if they would work for me? I saved a picture of them from the Ebay ad if anyone wanted to see the info printed on the filters housing.
Thanks.

I will get that s/n for you and report back soon.
I think that I will install both filters into the TR4. That may offer more compatibility.
I see your reason for asking about the s/n. As earlier ones used an 8-pole "can" style filter.
Thanks,
Bob N3JQD

5327. WTB: 160 xtal for R4C - 12.9 Mhz xtal

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-05-08 15:07:00 UTC
From: Rich Hallman - N7TR
Topic: 5327 Message: 5327

Looking for a 12.9 mhz xtal for the R4 / T4.

I know I can get the 12.6 mhz xtal, but looking for a 12.9 so the 1.8 mhz scale starts at 0 on the tuning dial.

Thanks...

If you can't find a 12.9Mhz crystal check with International Crystals in Oklahoma City, OK. They can make you one for about $22 plus a few dollars USPS shipping.

http://www.icmfg.com/hamradio-manufacturers.html

They have an toll free 800 number you can call. I buy all my Drake crystals from International Crystals and I have never gotten a bad crystal yet.

Rich

DigiKey has 12.8 and 12.96

If I were to use the 12.8 would this mean that 1.8 would be at 100 on the R4b dial?

I have been using a digikey 14.0 mHz crystal in my 2B for several years now as a 20M crystal.

The price is right I used a dead crystal for the base.

5334. [Drakelist] FS: Unique Drake Service Supplement CDs

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-05-10 20:02:14 UTC
From: Garey Barrell
Topic: 5334 Message: 5334

Here is the information that Drake left out of their manuals!

Unique supplemental service information CDs available for the Drake TR-4, TR-4C/Cw/CwRIT, A, B and C
Lines, 2-C / 2-NT and the 2-B receiver.

High resolution color photos of the under chassis and individual PC boards of each unit, with all
parts identified and keyed to a parts list make it easy to locate any component. No more trying to
trace wires through bundles, etc. This information is not available elsewhere and really makes a
difference in servicing these units.

These CDs are NOT just scans of the original manuals that were included with the equipment when new.
High resolution scans of the original manuals ARE on the CDs, along with scans of manuals for
associated equipment such as the C-4, FS-4, MN2000, L-4B, W-4, etc.

Samples of these pages (at reduced resolution) and purchase information are at <www.k4oah.com>.

5335. 4 line vfo

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-05-12 14:29:09 UTC
From: yash@aol.com
Topic: 5335 Message: 5335

I have been looking at the 5-6 digital vfo kits that are on the market. I have written all of them about adapting to the drake 4 line. None have offered any info or help ,other than they make a vfo kit but have no applications info to give. Has anyone in the group done such a conversion> would like to build up a digital remote vfo. I don't want to reinvent the wheel if some one has worked this out,and also I do not have the background to design a interface circuit if needed. With all the kits out there sure seems like a do able project.
thanks

From: Bry Carling
Topic: 5336 Message: 5336

REDUCED EVEN MORE (Next stop eBay)

Variable AC transformers. With front panels.

Two 250 watt "variacs" - Each designed for 0 - 250 V AC at 1 amp, 60 Hz.
Can be used at 120V AC also.

These are conservatively rated and can probably handle 1.5 to 2.0 Amps at 120V easily.
They are three terminal, open frame Powerstat variable transformers with 1/4" shaft.
One has a knob.

Now available for $15.00 each plus shipping

Next stop eBay if nobody wants them.

73 & thanks for looking - Bry, AF4K

Bry,
I'll take one. Do you want PayPal, or USPS Money Order. PayPal can be done as gift, so that neither of us incurs a fee, if you are willing to accept that. If not, I can get a USPS Money Order on Monday, and send it off then.
Also, have been meaning to contact you, to see if you are interested in a bunch of old crystals that I have. I haven't even looked at them in a while. Many are the old style, where the cases are sealed, and screwed, rather than soldered.
If you might be interested, let me know, and I can get you a count, and a list, and some decent hi-res photos of them. All are stashed away in a nice heavy duty and padded metal box, which appears to be military, of some sort. I just need to get them out from under the counter they are stashed below.

73,
Dan

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

5340. Drake 2A crystals.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-05-17 03:36:04 UTC
From: a_average_joe
Topic: 5340 Message: 5340

Just picked up a 2A and it's full of CB crystals. Sombody have a 40 meter (11 Mhz) crystal? I did find a fella selling the 11Mhz crystals on the net, but thought I'd asked here first. Other than being covered with yellow cigarette film and paint specks, it seems to be working and just to damb nice a receiver to part out.

5345. TR-4 question

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-05-19 22:09:42 UTC
From: km5wx@bellsouth.net
Topic: 5345 Message: 5345

Several years ago I purchased a tr-4 with ms-4 rv-4c. The rig had been in a fire and was repaired by a gentleman in Memphis that is not a ham but restores boatanchors as a hobby to keep for his collection or sell. My question is there is no visible serial no. on the rig . It operates excellently. Did all of the tr-4 rigs have a copper chassis? This does not appear to be copper. Understanding that it was in a fire maybe the chassis is very stained or he may have constructed a new chassis out of some other material. So as I said my question is did all the tr-4 have the copper chassis or did a later model possible had galvanized steel, aluminum or just plain steel. Thanks for the info in advance. KM5WX Richard

My TR-3 has a copper chassis.
My TR-4 has a copper chassis, but I don't think its the later serial numbers.
Garey calles it a TR-4B.
My TR-4C has a steel chassis.

Are any tube types silkscreened onto your chassis? I believe the chassis weren't really copper but copper plated onto a steel chassis.

Richard -

To my knowledge, ALL TR-4 transceivers came with a copper plated steel chassis. The TR-4C had a steel chassis with a surface treatment similar to cadmium plate.

I wouldn't think it would be worthwhile to fabricate a new chassis. How many dial discs does the PTO have? If there are two, it may be a TR-4C with a TR-4 front panel on it. If a single dial disc, it could still be a TR-4C chassis with the TR-4 PTO. There may be other 'mix and match' possibilities, but that's all that come to mind.

If you can send me a photo of the top and bottom chassis I can probably identify it.

Hi Lawrence:

The knobs never had a red pointer because there is a planetary gear reduction connected to the shaft. You are missing the red metal pointer that has a small round hole that friction mounts by pushing it onto the larger part of the shaft.

Painting a line on knob would not work because the knob rotates many times faster than the planetary gear reduction. You should ask the Forum" if anyone has a spare red pointer for you to purchase.

There is a slit in the end of the metal circle that pushes onto the shaft so that it can expand as you push it on the assembly. That is how its held in place.

You could temporarily make a pointer, but, be care not to push it too far onto the shaft where it may hit the panel and scrape off the paint. It must be perfectly flat so when it rotates, it doesn't touch the panel.

Al,
This receiver has a planetary drive but it appears that it is not the original Drake drive. It looks to be much larger than the Drake drive as it covers up the inner circle of numbers and a little of the 'circle line'. The knob is not Drake and this 'assembly' has no pointer. Looks like I need to find the whole planetary assembly. I'll see what I can find and I may still need to get the knob from you if the assembly does not come with one. Other than the preselector problem, the receiver is almost perfect, not a scratch anywhere and the copper is perfect. Thanks for all your help.

Lawrence

Lawrence:

Well, sounds like quite a modification!
If you do not have a source for the separate assembly, You can send you radio to one of the drake techs listed at www://wb4hfn.com or buy a parts only R4B from ebay or qth.com etc.

I know you don't need the extra expense, but the drake repair guys are excellent and have repair parts///also

Try the drake net today or next sunday at 2000Z at 7238 plus/minus Qrm. You can inquire about the part.

I do not know if the drake techs will be back from Dayton today for the net but Next sunday for sure!

Al,
This receiver has a planetary drive but it appears that it is not the original Drake drive. It looks to be much larger than the Drake drive as it covers up the inner circle of numbers and a little of the 'circle line'. The knob is not Drake and this 'assembly' has no pointer. Looks like I need to find the whole planetary assembly. I'll see what I can find and I may still need to get the knob from you if the assembly does not come with one.
Other than the preselector problem, the receiver is almost perfect, not a scratch anywhere and the copper is perfect. Thanks for all your help.

Lawrence

Hi Lawrence:

The knobs never had a red pointer because there is a planetary gear reduction connected to the shaft. You are missing the red metal pointer that has a small round hole that friction mounts by pushing it onto the larger part of the shaft.

Painting a line on knob would not work because the knob rotates many times faster than the planetary gear reduction. You should ask the Forum" if anyone has a spare red pointer for you to purchase.

There is a slit in the end of the metal circle that pushes onto the shaft so that it can expand as you push it on the assembly. That is how its held in place.

You could temporarily make a pointer, but, be care not to push it too far onto the shaft where it may hit the panel and scrape off the paint. It must be perfectly flat so when it rotates, it doesn't touch the panel.

Al,
Thanks. I just got this R4 B and the previous owner changed the preselector knob to a two piece non Drake knob. It doesn't have the red pointer so its hard to know exactly where the preselector is set. Do your knobs have the red indicator?

Thanks,

Lawrence

Be VERY careful on the ones you find. I thought I had a good, NOS one, but it tunes backwards when you look at it closely and must be for the TR6, which goes that way. It sure looks like the T4XB or R4B, but won't work!!! Drake may have sold these out late, and honestly thought they were selling 4B ones.

My T-4XB's dial is severely browned in one portion from sitting unused for years in sunlight (I presume).
Anyways, I'm looking for a nice clear, flat replacement. Anyone have one they wish to sell or know of one? I've checked ebay for quite some time with no luck.
tnx
Bob

From: Bry Carling
Topic: 5368 Message: 5368

FOR SALE:

160m, 80m, 40m, 20m, 6m, 2m original, old FT243 rocks... for CW and AM etc.

Several people have asked for the availability of some original amateur band FT243 Crystals.

I do have a limited number of these for 80m, 40m, 20m, 6m and 2m bands.

I have a few more to add yet on 40m - 6m - 2m but the rest are ready...
The list and buying buttons can be found at:

http://www.af4k.com/FT243_CRYSTALS_Originals.htm

I have a Drake B-line that I have had for 15 plus years. I has been is storage for 10 plus years. I am interested in bring it out of storage and restore it. The station consists of a R4B, T4XB and AC-4 Power Supply with speaker & cabinet.

My question is I need someone that is exprenced in restoration/refurbishing to post a set of steps that I should go through to accomplish this. I am an experience Tech (now retired)and feel confident that I can do the restoring, but would feel better to have someone that has done this to point me in the right direction.

Thank you in advance for your helps.

Will W5KD

Step one is to order the CD of service information offered by Garey Burrell, there is a lot of stuff there that is not available anywhere else. Another step is to order the rebuild kit for the AC-4 made by The Heathkit Shop, it replaces all the perishable items such as filter caps and diodes and puts all on a circuit board. Easy to install and not expensive. Other than that clean all the switches. My guess is that it all works but keep in mind that electrolytic caps don't like being in storage. You can test the AC-4 on its own by shorting the switch pins on the plug and measuring the voltage. The one that is critical is the bias voltage, if its not there the final tubes will be ruined very quickly.

One step Richard left out is to order the capacitor replacement kits for the R4B/T4XB from Hayseed Hamfest (www.hayseedhamfest.com) to replace those electrolytic capacitors with good quality, original looking replacements. I also replace the paper ones with orange drops or similar capacitors from Mouser (www.mouser.com). Finally, the cathode resistors on the T4XB (15 ohm 1 watt, if memory serves) are likely very high and should be replaced. I'm sure Garey will have more ideas when he awakes, hi.

Will -

You've had some good advice so far.....

Certainly replacing all electrolytic caps in all three pieces is the safest and best approach. It will make them good for another 30 years. I don't replace the film capacitors routinely as they seem to be fine in almost all cases, and are easy to troubleshoot IF they cause a problem.

If you just can't stand it, you CAN turn them on while you're waiting for the new caps to arrive! FIRST, check the fuses in both units. The AC-4 should have a 5A fuse, (replace with a 6-1/4A if necessary), and the R-4B should have a 3/4A Slo Blo.

Wire a power cord with a series connected light bulb, put in a 60W bulb, plug in the receiver and turn it on. The bulb should glow brightly for a second or two and then dim as the receiver warms up. If the receiver seems to be working ok short the bulb or plug directly into the line. If the receiver works with no hum or other apparent problems it should be safe to use. DO NOT run it unattended for at least several hours just to be careful.

Use the same cord on the AC-4 with a 100W bulb. Again the bulb should glow brightly for a second or two and then dim. Be sure and set the controls as described in the manual before turn-on, especially that the FUNCTION switch is in SSB. WATCH the PLATE meter, if ANY current is shown, shut down immediately. IF ok, turn GAIN to minimum, switch to CW, and quickly adjust the BIAS control on the AC-4 for 70 mA of PLATE current. If all ok, again safe to use but ONLY when ATTENDED. IF the BIAS supply fails, the transmitter will 'key', and the PA tubes and/or other components WILL be destroyed unless shut down immediately!

If you're more patient than I am, just wait for the new caps and rework to be done! :-)

I think it would be useful to have a check list with a procedure for firing up equipment which has been in storage for long periods. Much will be generic and applicable to anything, some will be specific to a given equipment. To some degree the same procedures will work for both vacuum tube and solid state equipment.
While electrolytic capacitors do become degraded when stored for long periods without a charge they often stay good for surprizingly long periods and should not be changed simply because of age. They can be tested for leakage and capacitance value.
Many other components will age well and should not be changed without checking them. This applies to carbon composition resistors. While they tend to go up in value with age not all do and the change varies a lot with the brand. In particular Ohmite and Allen-Bradley resistors seem to stay quite stable.
Old paper capacitors should mostly be changed out on sight. The poor ageing of these caps was well known when they were made, however much Drake equipment has no paper caps but rather plastic film capacitors, which are very stable and long lived. The same is true of disc ceramic capacitors except for some of the very high K types. COG

caps are very stable and extremely long lived. Failures in ceramic caps come mainly from cracking due to stress on the leads.
There are mechanical problems with all old equipment.
Drake uses screws to make ground connections in many places. When some oxidation forms around the screw the resistance of the connection becomes high. The cure is simply to work the screw to clean its contact with the chassis.
Any type of plug is subject to corrosion and should be worked or cleaned.
All types of switches are subject to corrosion and should be treated with a contact cleaner and worked many times to clean the surfaces. Sometimes the application of a special grease like General Cement Tuner-Lub will help to prevent re-oxidation of cleaned contacts.
The same is true of tube sockets and pins. Sockets can be cleaned with contact cleaner by working the tube in the socket. Tube pins sometimes become corroded enough to require cleaning with a wire brush. This should be tried when one finds a tube that is inconsistent or that checks OK on a tube checker but doesn't work. Sometimes the sockets contact a different part of the pin so the tube will work in one socket but not the other.
Its possible for solder joints to become high in resistance due to chemical changes in the solder or mechanical stress or failure of the original soldering to properly melt and flow the solder. Sometimes these are known as "sugar" joints because the crystalization of the solder looks like sugar. The cure is to heat the joints and re-flow the solder with, perhaps the addition of a small amount of new solder and flux.
Dirt is always the enemy but sometimes cleaning will do more damage than leaving things a bit dirty. Its always better to keep things clean to begin with.
Thats what I come up with off the top of my head, I am sure others can add to this.

Contact cleaner works on pots but there is a special
cleaner for pots made by Caig labs who make Deoxit. This has
a lubricant in it which will keep the pot from becoming
noisy again.
It _is_ possible for a pot to have a damaged resistance
element so one that is persistently noisy or intermittant
will probably have to be replaced but cleaning is always
worth trying.
I should have included pots in my little list of things
to check on equipment which has been in storage.

Sorry, Richard. Although I agree with a lot of what you posted, I think it bad policy to NOT recommend replacement of these old electrolytics. They are just too cheap to risk the power transformer in the R4(x) (unobtainium, unless you find a donor), and the finals et al in the T4X(x) if (NO when) the bias supply fails!!! The other caps, resistors, etc. are owner's choice, but I won't "re-start" any old boatanchor without replacing the electrolytics (and Black Beauties, if appropriate). I may be wrong, but I haven't lost the unobtainium parts yet, and will continue to advise newer list members to do the same. My .02 worth, and not worth that much.

Topic: 5369 Message: 5377

Don -

This discussion comes up every once in a while.

Certainly if you just want to 'fix and forget it', replacing all electrolytics and _paper_ capacitors is a reasonable approach. IF this is your ONLY station, or a piece of critical equipment, replacement makes sense in the interest of reliability.

That said, the fact remains that there are literally thousands of Drake radios out there with the original electrolytics in them, and working fine.

When I get a 'new' radio, the FIRST thing I do is check the fuse. You wouldn't believe the things I have found in those fuse holders. Anything from an aluminum foil wrapped fuse to a piece of #8 copper wire! Needless to say, ANY sort of failure under these conditions is a death sentence for the radio, and perhaps for others if you typically leave your equipment 'ON' and unattended.

The next thing I do is hang the ESR meter on each electrolytic. Over many years of acquiring, and (very occasionally) selling Drake and a few other brands of radio gear, I have only found four or five defective capacitors with the ESR meter. High ESR is a definitive indication of a failing or failed electrolytic. It may or may not short, but certainly ripple levels (hum) will increase. Obviously if there is one section bad in a multi-section cap the whole thing is replaced. Only ONE capacitor was found that was actually shorted. The light-bulb trick will find and protect against this one too.

As an aside, 'modern' DC-DC converter power supplies are capacitor killers. I have yet to find a display monitor or other similar unit with a DC-DC converter power supply that did NOT have at least a couple of high ESR caps. The higher ripple currents just (h)eat caps up.

I have found a couple of leaky film capacitors in Drake gear in the last few years, but it is still quite rare, and because of where they are used excess leakage is quickly apparent in operation of the unit. I also VERY seldom find a defective tantalum (epoxy dipped) unless it is being operated very near it's voltage rating, and so don't routinely replace those either.

Even less common is failure of the disk ceramic caps Drake used. The "+80 / -20, @ 16V" is the most common one to fail, followed by the larger value high voltage (0.1 @ 600V) and last the smaller ceramic bypass caps that rarely fail, and the ones that do almost always have had their leads stretched enough to break the encapsulation material.

The carbon comp resistors that Drake used were very high quality, typically Allen-Bradley, and again are almost always within tolerance _unless_ the radio has obviously been mistreated. You know the ones I mean, they look like they have been stored in a chicken coop for the last 40 years. VERY occasionally one of the very high value resistors 6.8 - 22M will go up in value, but in most cases the circuit will still work as designed.

One last thing and I'll shut up. The Voltage and especially the Resistance tables in the Drake manuals are not always accurate. There are cases where the schematic has changed, changing, adding or removing a resistor, and the table is unchanged. Another difficulty with the Voltage table is that the Grid of oscillator tubes MUST be measured with a VTVM, with the 1M resistor in the probe tip, to get an accurate reading. Most any DMM lead will kill the oscillator, drastically altering the reading. If you don't have a VTVM (?) wrapping a 1M resistor around the probe tip and probing with the other lead will give you a reading about 10% low with most DMMs. The Resistance tables, especially the readings that go back through the power supply filter caps, are highly inaccurate. The value of the resistors are secondary to the parallel paths encountered, as well as the polarity of the Ohmmeter probes. If you get a strange reading on one of these, reverse the meter probes. The reading may be closer, or it may be even further off! :-)

Don Cunningham wrote:
> Sorry, Richard. Although I agree with a lot of what you posted, I think it bad policy to NOT recommend replacement of these old electrolytics. They are just too cheap to risk the power transformer in the R4(x) (unobtainium, unless you find a donor), and the finals et al in the T4X(x) if (NO when) the bias supply fails!!! The other caps, resistors, etc. are owner's choice, but I won't "re-start" any old boatanchor without replacing the electrolytics (and Black Beauties, if appropriate). I may be wrong, but I haven't lost the unobtainium parts yet, and will continue to advise newer list members to do the same. My .02 worth, and not worth that much.

Garey,
First, I don't EVER want you to "shut up" at all!!! Every time you post I learn enough valuable information that I save the message. I can't get you to write up your "Drake Diagnostics" book for all of us to buy, so I'm saving the bits as I get them, HI.

I never disagree with your recommendations, but am finding (off line mostly) that some of the guys are new to this "old" gear, and don't have the test equipment that even I do, much less some of you that are much smarter than me (you, Evan, Gary, Ron, Jim, Dino, etc etc). I just hate to discourage them with the posts that alude to buying a BUNCH of expensive test gear just to maintain a fun rig. I have found over the years that if I replace the parts I mentioned, the Drakes play nicely for years, with only occasional hiccups. I do think it would be good if one of you "guru's" would post what test equipment we should have to properly care for our Drakes sometime. Not the "optimum", but reachable. I think all hams should have a good meter (voltage, resistance, etc) as they are essential, but then I have gone a little overboard otherwise. Also, I'm not sure that the ESR meter that I bought after you recommended it is still available, and the ones I find are pretty pricey. My kit was under $75, and worth every penny.

As you said, few of the caps I replace fail the ESR test, so I may be wasting money, but at least Tom has my picture back on the piano since I have bought several, hi. I too feel the replacing of the film ones is probably a waste of money, but I feel better. The resistor I find most that has drifted up are the cathode resistors, that's why I mentioned them. ALL of the ones I have replaced were 20 ohms or higher, so maybe the previous owners abused them some.

Now it's DEFINITELY time for me to shut up, what little I know.

73,
Don, WB5HAK

Hi Don and Garey:

I recapped my TR4 and B line a couple of years past, but forgot the black beauties on the various boards. Have they been known to cause problems?

Do they self destruct or screw up the circuit? Should they be replaced with orange drops as a preventative?
thanks ..Al kc9ys

One step Richard left out is to order the capacitor replacement kits for the R4B/T4XB from Hayseed Hamfest (www.hayseedhamfest.com) to replace those electrolytic capacitors with good quality, original looking replacements. I also replace the paper ones with orange drops or similar capacitors from Mouser (www.mouser.com). Finally, the cathode resistors on the T4XB (15 ohm 1 watt, if memory serves) are likely very high and should be replaced. I'm sure Garey will have more ideas when he awakes, hi.

Alan,
To my knowledge, there are NO black beauty caps in any of the drakes. Some of the "film" caps are black, but not the infamous ones.
They should be fine, even though I replaced mine, hi.

Al -

No 'Black Beauties' in Drake. There are a couple of film caps with
black sleeves and white ends, but those are fine.

'Black Beauties' refer to a much earlier capacitor made by Sprague.
They were oiled paper and foil that was packaged in a plastic housing.
They were notorious for leaking oil from cracks where the leads came
out, VERY leaky (electrically), and generally junk. There is another
variety very similar in construction that had very narrow color stripes,
similar to resistor color codes, but very narrow lines and wide spaced,
called 'bumble bees'. They are still highly 'prized' by guitar amp
guys, whose primary goal is distortion. A leaky coupling cap biases the
grid positive, causing tremendous distortion in an amplifier.
Unfortunately, (or fortunately,?) they are highly variable, and of
course get worse with use. They could get similar, stable, results by
putting a high value resistor in parallel with a 'good' cap, but .....

Al,

No BB's that I know of…

BTW, you need a 120MM fan grill for those 120VAC fans Evan gave us. I might have an extra floating around…

Also, I found a nice polishing compound that gets any scratch out of silver finished front panels. Going to try on the Galaxy's and B-Line's edges.

I'm guilty. I recently replaced mine in an R-4B, thinking they were black beauties. No difference in performance detected after I replaced them with "yellow jackets." Since then, I've acquired a Sencore LC-102 cap analyzer to better assist with these decisions in the future.

> They are still highly 'prized' by guitar amp guys, whose primary goal is distortion. A leaky coupling cap biases the grid positive, causing tremendous distortion in an amplifier.

Darn, there are easier and less expensive ways to accomplish that goal but try reasoning with them. I find it incredible that some folks are paying more than $20 ea. for these old, leaky caps that have been cut out of old 1950s era equipment.

Don, Richard and Garey,

First I would like to thank each of you for taking the time to provide the kind of information that I was looking for. I will read and re-read all the information you have provided and then begin the list of items I need to at least start restoring the old Drake B-line.

The equipment was functioning perfectly when I stored it away. The reason for storing it was a move from one part of the country to another. It has been in storage for at least 10 years. It has been keep in a good location and has not be stored where it would come in contact with any mositure. The reason I have never taken it out of storage is beacuse I purchased (new) an ICOM 746PRO and it has been my number one rig since 2002. I recently joined this Yahoo Group and have read many of the posts. It started me to thinking about my old Drake gear. At one time it was my number one station and it was a pleasure to operate.

I no longer have a full setup of test equipment, but don't think I would need it to take the steps suggested. It would be nice to have a scope, signal generator etc once again, but at my age I can't justify spending the money to just restore three pieces of equipment.

Once again many thanksfor the quick response to my questions. I will keep you posted as to my progress. If you think of any other ideas please post them here as I will check the posting often. One other thing I do have all the manuals.

73,
Will W5KD

Anyone have a photo of these bumble bees? I had thought they
were black
beauties? What rae the ones with the blue bodies?

There were a number of similar caps made at the time.
The blue cased ones may be "Cub" caps made by
Cornell-Dublier. There were a wide variety of Bakelite
encapsulated caps around the late 1940 and 1950's. They were
supposed to be more resistant to degradation by moisture
absorption than the earlier caps in wax filled paper tubes.
The BB caps also used plastic impregnated paper, supposed to
be more stable and have lower loses and better temperature
characteristics than plain paper caps. Unfortunately, there
were evidently production problems with the BB's causing
early failure. They were _supposed_ to be deluxe, high
performance caps and I suspect were a disaster for Sprague.

Here is a photo, (along with commentary!,) of Bumble Bees and Black Beauties. There is another type (Brand?) of Bumble Bee that has very, very thin, separated, color stripes.

One easy way to spot troublesome caps, regardless of brand, is to look for a longitudinal 'seam', with the leads coming out from between the two halves. Later, better quality caps are assembled like the ones in Drake gear, tube body, filled with epoxy, or Orange Drop types just molded in epoxy. Of course, aside from the construction, the switch from various types of paper impregnated with oil to poly film for the capacitor insulation layers greatly improved stability and leakage characteristics.

Looking for this photo <http://tinyurl.com/3w7453w>, I came across several mentions of 'aftermarket' Bumble Bees apparently being manufactured today for guitar aficionados.!!* <*http://tinyurl.com/3uopumg>

The multiple colored rings were a standard method of
coding capacitor values and were used by several
manufacturers. There was at least one other brand of plastic
cased paper caps with stripes, these were in a white case.
Other, similar, caps, including the later Sprague Telecap,

had the values stamped on the body rather than the stripes. Sprague Telecaps look just like Black Beauties but are described as _dry_ in the Sprague ads. But one line of the ad says something like these Black Beauties... I think the early failure of BB caps became apparent within a couple of years of their manufacture. All paper caps become degraded with time. I've seen several explanations of this but don't know which is the right one. When these caps were current there were voltage derating charts for them, the lower the operating voltage compared to the rated voltage the longer the expected life was. At rated voltage all paper caps had lifetimes of around two years, at half voltage around ten years or longer. Part of the problem was supposed to be chemical changes in the paper due to the applied voltage. Impregnating the paper with oil or wax increased its dielectric constant allowing thicker paper to be used for the same capacitance thus increasing the allowable voltage. Oil caps were very common for high voltage purposes and were supposed to be more stable with time than wax impregnated or plain paper caps.

The Sprague Black Beauty and other caps of the time used paper which was impregnated with plastic and had molded plastic cases. The idea was to improve both the dielectric characteristics and stability of the cap and to protect it from moisture. Some of these, like the BB's, were also impregnated with oil. The BB cap had an oil-filling tube at one end which served as one of the connecting leads. The tube was sealed after filling by inserting the lead wire in it and soldering. If the heat applied to the lead when installing the cap is too high the solder will melt allowing the oil to leak out. That causes rather rapid failure of the cap. I think, however, that this was not the only problem with BB's, for instance, I have dissected several BB caps including some that were intact and still had oil in them. _All_ had distorted windings. I don't know the cause of this but suspect the process of molding the cases may have distorted the windings. Also, it was a common practice to fine tune the value of a cap by compressing the winding a bit but that changes too many other things and I don't think its what I am seeing. BB caps have a reputation for cracking and splitting which tends to reinforce my idea that there was a problem with either the material or process used for molding. Other plastic encased caps do not seem to have this problem. Unfortunately, BBs were widely used in some very high quality equipment.

While BB caps seem to have a set of vices all their own all paper caps become degraded with time. If the application is such that the voltage on the cap is well below its rating the life can be very long but all will eventually develop low capacitance and increased dissipation. These effects are

mostly not true of modern film or high quality ceramic caps
although some are better than others. Measured dissipation
factor and leakage of modern film caps is vastly better than
what I get from older paper caps even those in good
condition.
BTW, its important to check parallel resistance AKA
leakage. While this is known to be important for
electrolytic caps it can also be a problem for non-polar
types. I have some molded paper caps which check OK for
value and dissipation but have high enough leakage to make
them non-functional in the circuits they were used in. This
is especially important for coupling caps and cathode or
emitter by-pass caps where leakage can affect the bias on
the active element.

From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5396

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

5397. UV-3 Manual for sale

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-05-30 17:06:46 UTC
From: Dan Galligan
Topic: 5397 Message: 5397

Hi all. I am in process of preparing to move, and recently found the original manual for the UV-3, that I sold a couple of years ago. When I sold the radio, I thought I had it, but could not locate it, or the manual for my Kenwood, and had to sell the radio, without the manual. A couple of weeks ago, I found those two manuals, plus a few others I had forgotten I had, in an obscure location in the house. The others are for radios that I either currently own, or am likely to buy another, so I'll hold on to them, but, I don't see myself ever getting another UV-3, so it seems only right to get the manual in the hands of someone who would appreciate having it.I tried to go through the records of where I sold my UV-3, but can't find who bought it, so I'll offer it up here. It is in pretty good shape, and it does not appear to have any pages missing. I can take and email pictures, if anyone is interested. I am not looking to make money on it, I figure $5 plus actual shipping costs, should make it worth my time and gas to take a trip to the Post Office, to send it to someone, but if there is no interest in it, here, I'll then offer it up on eekBay, QTH and QRZ, for whatever the market value is. If interested, please reply to me direct, at w3rxo at mac dot com.

5398. Dial

Don -

Jim brought up a good point. I have scans of quite a few already, and just waiting until I can get some cash together to make some repros. I have a company to make them, but minimums are a little too big to take a chance on right now.

If you can scan at 600 dpi, scan it 'face down', i.e., through the plastic, and 'face up', lettering right on the scanner.

I've been trying to remember to do this when I have a radio that far disassembled, but so far I've only got Siltronix 1011C and Heath HW-7 (damaged). I don't have any plans to do repros myself at the moment, but I think it would be a good idea to build a library. Whatever I do get will be available to whoever wants it.

I'm also trying to do more photo documentation of radio internals. Just did a TR-33C yesterday. Re-scanning original manuals and adding better photos may be in future plans (wonder where I got THAT idea...). One of my pet peeves is the abysmal quality of 90% of the scanned manuals on the internet.

Not to worry, I won't be duplicating the effort you've put into your CDs. :)

Mike -

Yes, there were two, a TC-2 and a TC-6. Both require a minor
modification to the T-4XC, 'borrow' the existing AC-4, and all switching
accomplished via the CC-1. The TC-6 uses three 6JB6 PA tubes for about
300W input, and the TC-2 uses a single 8643 for about 180W input.

Lee -

Yes, remember those are INPUT power, which is how transmitter power was measured when these were sold. OUTPUT power, which what is usually specified these days, is about 50% or a little less than those numbers. But yes, they were 'transmitters', not just converters like many of the other 'transverters' of then and now.

5418. value of drake gear.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-06-06 13:45:20 UTC
From: yash@aol.com
Topic: 5418 Message: 5418

Have a very nice Drake R4/T4X/ AC-4/ MS-4 all the gear is real clean and operates just fine. My question is why is the early 4 line gear worth next to nothing, when compared to the rest of the 4 line. I have owned a B-line,a C-line in the past ,both good performers,B being my choice between the two. I find the early 4 line performance ,from my ear and operation just as good as my B-line. Of course I never had the chance to run them side by side,and the mind can play tricks, they perform so close in real life operation,they seem almost the same to me. Watching QTH and Ebay I see the 4A and 4B gear go for twice the price all most all the time ,over the 4 gear. I realize that Drake made some mechanical and operational changes thru the years,but basic radio performance is not that different. I had a full Drake/Sherwood C line , and it was the BEST of the lot,but they will go for BIG $$$ used. I was just curious, so I thought I would as a few others opinions .
thanks for reading.

Hi,
There were some changes in the R4 to R4a that were desireable, mostly in the audio chain. However, I think its mostly the "age" thing for the R4 versus the R4a. Many R4's chassis are pretty ugly with corrosion. In fact, most R4a's are the same way. Now, for the T4x, that series went through to the T4xB. And not much difference there, so price is based only on age/or condition. Selling the T4x by itself should be straightforward, as well as the MS4 and AC4. Then we come to perception.

There is a perception out there that the "late" R4a or a R4B is the more desireable of the Drake lines. Hams cite mostly technical information, and some will talk about parts availability. The reality is somewhere else.

If your R4 station is above average, then it would or should be priced about the same as an early R4a, in my opinion.

If you go to www.wb4hfn.com and click on the drake area, there is a page on pricing of drake radios. I believe Ron Baker keeps it pretty well up to date.

The Ac4, is probably in need of a rebuild. Most all the Drake power supplies are now of an age that its good insurance against catastrophic failure. I've done all mine including the L4PS.

Dale,
One big difference between the T4X and T4XB is filtering. MUCH better SSB carrier supression and therefore cleaner output. That said, many of them are on the air and doing fine on a non-crowded band, hi. Otherwise, appearance, etc. like was said. It is getting rough to find a truly clean copper chassis on these, even the B Lines.

5431. T4X Crystal Question.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-06-08 02:40:10 UTC
From: Bob Macklin
Topic: 5431 Message: 5431

I have a 21.1MHz crystal in my R4A for 10Mhz WWV and 30M.

The T4X book says to use a 20.8 MHz crystal for 10MHz. WHY?

Both the R4A and T4X use the same frequency crystals for 40M and 20M. Also the 10M band crystals are the same.

Is there a reason I cannot use a 20.1MHz crystal in the T4X for 30M. That makes the dial direct reading.

I cannot read the crystal table in the T4XB manual I have. But the T4XC manual has the same 20.8MHZ for 10MHz to 10.2MHz.

Is there a reason for this peculiarity?

More to the point, adding an RIT circuit introduces another node where drift
can potentially occur.

I've added a RIT to my R-4B.

Assuming the PTO is similar (with the terminal for FSK) then it should work fine on the R-4.

It gives just a small adjustment... a couple of hundred Hz only.

There's a copy of the schematic in the Files area on the DrakeRadio site.

I personally don't see the need for adding an RIT control to an R4<any> receiver. The only reason I can think of would be if that person always operates their Drake twins in "transceive". Personally, if I wanted to operate transceive all the time then I would use a transceiver such as a TR3, TR4, or TR7.

having said all that, if anyone wants to add an RIT control to their R4<any> receiver than that's entirely up to them but I simply don't see the need to do something like that.

OK here is where the rubber meets the road. When I left Virginia the CARS and VBARC organizations gave me a Drake TR-4 which needed T&R. I do not have any T&R equipment. Tonight I went to the San Antonio Radio Club meeting. They meet at the only Ham Radio store here, which also has a repair shop. I explained my problem and they said that on the final Saturday of July the store would be open but not the shop, and I could use the shop then. What I hope to accomplish in the mean time is to try to fix what I can at home and use what time I have in the shop for the major problems that I need the test equipment for. For example I know I can wire the microphone jack and plug at home. There are several different problems, so I am going to address each one in a separate post. I am looking forward to your ideas with gratitude and enthusiasm.

5439. Drake TR-4 T&R RX can't hear

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-06-10 04:06:41 UTC
From: Forrest Plumstead
Topic: 5439 Message: 5439

When I first got the radio RX worked just fine, then it started to go down hill.

- I get the rushing noise from the speaker so the AF is ok but I can not pick up any signals not even from my make-shift RF Gen or even my HW-8 sitting right next to it. First suspect blown filament. I turned out the lights in my shack turned on the radio and sure enough found a tube not glowing. Sadly it was a TX tube. (See TX in my next post)
- There is a related problem: At first the white noise coming from my speaker is weak. But if I jiggle the Sideband switch I get static noise then the white noise increases. At first when this happened the volume would change as I adjusted the RF Tune control. Now that has no effect.
- Related to the Sideband Switch, the knob came off the other day and a spring clip fell out. I have not been able to put the knob back on securely since.

That's about it for this segment I look forward to your thoughts, ideas, and suggestions.

5440. TR-4 T&R TX does not talk.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-06-10 04:22:12 UTC
From: Forrest Plumstead
Topic: 5440 Message: 5440

At first this was **The Major Problem**. TX would tune up on CW but there was no modulation. I think I might know what the problem is now. In the back of the radio next to the leading edge of the RF cage are two identical tubes with shields in front of two "cans". These are 12BA6s and they are IF amps. The one closest to the edge of the chassis is the RX IF and the one closest to the RF cage is TX. Even in the dark it was hard to check the filament glow of these two tubes. Finally I saw the one for the RX then I touched the envelope of the TX tube and it was just barely warm. Touched the RX and burnt my fingers. (Note to self get some burn ointment).

Does anybody have one of these floating around in your junk box? Also a previous owner left the shields off. Please contact me off list.

5441. TR-4 T&R Loading Cap sticky

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-06-10 04:29:40 UTC
From: Forrest Plumstead
Topic: 5441 Message: 5441

While tuning in CW the Tune Cap will give you a dip, but the loading cap is sticky until the 12:00 position then it moves freely and the power jumps up considerably, but the Plate current is on the high side. Have not taken the RF cage off yet and looked inside.

The manual says that the PA tubes are the only ones that you need to tune when you change them, but I don't see the tuning procedure in the manual. Are my aging eyes getting that bad? How do you balance and tune the PAs when you put in a new set?

The is a section on neutralizing. Balancing is best
done using a tube tester but can be done by measuring the
voltage drop across the 15ohm resistors in the cathodes.
First, make sure the resistors are all the same value.
Carbon composition resistors tend to increase in value with
age and heat but different brands drift at different rates
so some of the resistors will be OK and some not. They can
be replaced with film resistors if out of specs. There is
some controversey about just how closely the tubes have to
be matched. It varies from very closely to not at all.
Neutralizing is done to prevent oscillation from
positive feedback from plate to grid of the tube. A
capacitance is placed in the circuit such as to form one arm
of a bridge circuit. The conventional technique is to remove
the screen voltage from the amplifier. That can be done by
unsoldering a wire on a feed through cap under the chassis.
Then peak up the driver on about 20 meters and monitor the
output with a receiver or sensitive oscilloscope on the
antenna jack. Adjust the driver and plate tuning so that you
can see a signal and maximise it. Then adjust the
neutralizing cap to minimise it. Then go to 10 meters and
refine the adjustment. The null is never perfect but should
be quite good.
Now, reconnect the screens and attach the transmitter
to a dummy load. Now, adjust the driver on 10 meters and

carefully bring up the drive until you see some output and can dip the plate. Bring the drive up a bit more and redip. Watch the output power meter, either the one on the TX or (preferrably) an external one and adjust the loading for maximum, continue to juggle the loading and plate tuning dipping making sure that the maximum power occurs on the dip, that is, on the current minimum. If there is any tendency for the power to peak when the plate tuning dip is going up the stage is not neutralized. Since you are close to the right place you can refine the neutralizing tuning by watching the direction of the output power when dipping. On the side where the power is going up with increasing plate current make a very slight adjustment to the neutralizing cap to bring it downward and again check for co-incidence of dip in current with peak in power, they should be exact. Once you are there you should be able to tune for maximum power output without any spurious output or overloading of the tubes from going into oscillation. The usual symptom of oscillation is that the plate dip and output peak are not in the same place, and if the tube is allowed to operate this way for more than a few seconds the plate will become red hot. Usually, that will kill the tubes if allowed to persist for more than a couple of seconds.
Both plate tuning and loading must be done carefully on the higher bands because its easy to miss the correct spot and to tune on a false peak. If your power meter indicates unreasonably high output the amplifier is almost certainly oscillating.
All this is easier to do than to describe. A WARNING! you are dealing with high voltages with enough current available to kill you in the RF amplifier section, BE CARFUL. The same rules of safty that apply to the highest power transmitters also apply to the little guys, 600V will kill you just as dead as 6000. Make sure you use insulated tools, some that look insulated are not. Have a shorting stick and make sure you short the plates to ground when powering down. Keep one hand in a pocket. This is NOT overkill for small vacuum tube stuff.

Good description.. I find that if I start on 20m as described, the adjustment is easy using the 'dip and peak' method as is the removal of screen voltage. One big caveat, the wire on the screen feed thru is fairly large, and wrapped around the terminal. If you get too aggressive, the ceramic WILL crack. Replacements can be gotten, but believe me they are NO fun to replace!!

Hello Forest,

You said;

"TX would tune up on CW..."

If that's true then that tells me that the transmitter's 9Mhz IF amplifier V15 (12BA6) is working as it should.

If V15 fails for any reason then the transmitter will not function in any mode, whether it be CW, sideband (USB/LSB) or AM.

Have you checked and/or swapped out the microphone/speech amplifier V18 (12AX7)? If V18 fails then CW would continue to work but sideband and AM would not work.

How do you have your microphone plug wired? The microphone plug should be wired as follows:

Microphone element to the plug's "Ring"
PTT to the plug's "Tip"
Ground to the plugs "Sleeve".

If your microphone is wired differently then that cold be the cause your loss of modulation in sideband/AM modes.

If you do not have the TR4 operator's manual then diagnosing problems will be a bit difficult. I recommend contacting Garey, K4OAH, about purchasing his TR4 CD which contains invaluable information about the TR4 including the operator's manual and clean schematics.

Hi Mike!

You bring up a good point. So I am rethinking things. V15 must have blown the filament sometime between the time I last tested the TX and last night. I checked continuity of the the V15 heater and it is open. So I will have to replace V15 then continue to for the modulation problem using the techniques you just described.

The mike is hard wired in I have a jack and plug that I have to wire in thanks for the instructions.

Yes I do have the operator's manual.

Forrest,

You said;

"V15 must have blown the filament sometime between the time I last tested the TX and last night. I checked continuity of the the V15 heater and it is open."

If V15's filament is open then all modes, CW, SSB, and AM, will fail to work. I think you may have meant "V18" (12AX7), the speech amplifier. If only one of V18's filaments are open then SSB and AM will not work but CW will continue to work. V15 is used in transmit ALL modes.

You should check the hardwired microphone wiring, it may be wired wrong or possibly a broken wire. I never cared for hardwired microphone cables.

Also don't discount the microphone itself. There could be a broken wire or bad solder connection. If the microphone element goes through the PTT switch assembly inside the microphone, a wire could be broken so check it to be sure.

One additional thought I forgot to mention.

If any tube has a "white" color on the inside of the glass envelope where the chrome coating once was, throw the tube away. The chrome coating is Barium and Barium turns white when exposed to air. Therefore, any tube that shows white on the inside means the glass envelope is cracked and the vacuum is lost. If power is applied to the filament when this occurs, the filaments will burn open, same as a light bulb will if the glass envelope is broken and 120VAC is applied to the filament.

From: dean_k5dh
Topic: 5451 Message: 5451

Hi all,

I bought a "fixer-upper" T-4XC and AC-4 at a hamfest yesterday. The T-4XC is complete except for the top cover of the RF cage. Anybody have one of these that they can sell me?

E-mail me at (my call sign) AT qsl.net

73,
Dean K5DH

Hello Dean,

I don't have a spare top cover but until you find one, either from a group member or from a parts radio found else where, you can make a temporary top cover out of perforated aluminum found at most hardware stores. Cutting the perforated aluminum is quite easy and can be done with a pair of tin sheers. I needed a top cover for a final amplifier enclosure on my Heathkit Marauder HX-10 and Apache TX-1 when I changed the final amplifier cooling fan so I cut one to size from perforated aluminum.

If you use this temporary method, make sure the clearance between the top and the final tube plate caps is 1/2 inch or more.

Just an idea for a temporary top cover until you find an actual replacement top.

5453. Birdies on several bands

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-06-12 17:31:51 UTC
From: yash@aol.com
Topic: 5453 Message: 5453

Was playing with my R-4 today and noticed a" birdie" very strong on 20 and 17 meters. Almost as strong as the cal tone.Showed up on 14150,210 ,275 and 335. On 17 showed up at 18120,135, and 145. Pulled the ant connection and gone,the R4 is silent except for a little white noise. If I pull the 2' jumper coax off the ant switch,but still connected to the R-4 , the birdie still there and as loud as when the switch is connected to the antenna. the rig seems to hear fine on both bands,just the birdie is always there. If I pull the jumper coax from the switch,short the coax, still there.
On the same antennas and antenna switch, my S-line does not have the birdies, nor does my Flex 1500. I also noticed on the R-4,This seems to come and go, that it is harder to tune to a CLEAN sounding audio on ssb,always seems a bit rough and not right on.
any ideas where to look.
thanks

Dale -

Not sure I understand what you are saying. You say "pulled the ant connection and gone." This indicates the signals are from outside the receiver, although you say if you disconnect from the antenna switch the birdie is still there???

Does the Preselector peak where it should for the frequencies you are hearing?

If the Preselector is mistuned, you may be hearing harmonics from the PTO, BAND oscillator, and/or BFO or various mixing products of the three.

Hi Garey
If I disconnect the antenna from the R-4 all goes quiet,nothing but receiver noise at a low level. If I reconnect the antenna at the R-4 and disconnect the other end of 2 foot coax that goes to the ant switch, all the birdies are back and loud. If I reconnect the 2 foot coax to the ant switch and switch the antenna to the drake,seems to hear fine except at the points of the birdies. I subbed the s-line in place of the R-4, no birdies,same for the flex 1500. ???

Date: 2011-06-12 19:33:39 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5456

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

Dale,

What happens if you connect a 50 ohm resistor (carbon or metal film) across the antenna connection? Do you still hear the birdies?

If you have a 50 dummy load, connect the dummy load directly to the R4 receiver. Do you still hear the birdies?

The only thing that comes to mind is that the RF Amp stage may be
oscillating due to the capacitance of the 2' cable. If you terminate
the 2' coax at the far end with a 50 ohm load are the birdies gone?
Can't say I've ever seen this, but with no antenna the receiver is
quiet, and 2' lengths of coax don't generate RF! :-)

Garey
what in the antenna input might cause this, what if T-1 is way out? or a bad 12bz6 ?

The only thing that comes to mind is that the RF Amp stage may be
oscillating due to the capacitance of the 2' cable. If you terminate
the 2' coax at the far end with a 50 ohm load are the birdies gone?
Can't say I've ever seen this, but with no antenna the receiver is
quiet, and 2' lengths of coax don't generate RF! :-)

Dale -

I would say that oscillation is pretty far down the list of likely possibilities. Try a different short length of coax in place of your 2' piece.

Try just putting a 2' length of hook-up wire on the center conductor of the ANT jack.

You didn't say if the Preselector was peaking where it 'should' for these frequencies according to the chart in the manual.

Garey
put a 2 foot chunk of wire on the antenna input, birdies all there, on 17 does about a S-8 on the meter, The pre selector peaks right around 20 just where the chart shows it to be.

Garey
sub the 1500 or the s line on the same feed,no birdies,but the s and 1500 could look at the coax a bit differant than the R-4? I will make some changes ,have 3 antennas ,a hex, a r-7 and a long wire , will see how the rig reacts. Why did the birdie's continue when connected to the dummy load?

If I pull the 2' jumper coax off the ant switch,but still connected to the R-4 , the birdie still there and as loud as when the switch is connected to the antenna. the rig seems to hear fine on both bands,just the birdie is always there. If I pull the jumper coax from the switch,short the coax, still there.
>>>> On the same antennas and antenna switch, my S-line does not have the birdies, nor does my Flex 1500. I also noticed on the R-4,This seems to come and go, that it is harder to tune to a CLEAN sounding audio on ssb,always seems a bit rough and not right on.

Its worth checking the coax especially for a flaky shield connection. It may be that the birdies are radiation from the receiver and are being picked up by the coax due to a bad shield but are not evident on another receiver because the conversion and oscillator frequencies are different. I also suggest using one of those receivers to listen for radiation from the Drake by means of both a short wire antenna, just to see if you can hear it and then by means of a short exploring coax with a small coil at the far end. Set up the Drake so that you are hearing birdies and then listen to that frequency with the second receiver while moving the exploring antenna around the chassis. It may be normal radiation.
Also, its worth making up another section of coax to go from the receiver to the antenna switch. If that makes the birdies go away or become much lower in amplitude its the original cable.
A word about "birdies". Normally, what is meant by this term are tunable spurious responses on a receiver caused by internal cross-modulation of the various signals in it. The more complex the receiver the more likely they are. By complex I mean mostly the frequency conversion scheme. A TRF reciever will have no birdies, a double-conversion set will have more than a single conversion one. It is typical for a "birdy" to tune faster than the desired signals because they are due to particular combinations of signals in the receiver and change rapidly when the receiver is tuned. they also tend to be less stable than normal signals. Birdies can also come from spurious oscillations in a receiver. These can come from defective by-passing or other sources of

unwanted regeneration. In designing any super-hetrodyne receiver its usual to make up a chart showing all the combinations and permutations of signal and oscillator frequencies that can result in spurious responses. In a double- or triple- conversion receiver they become very dense. Shielding is also a prime problem in design as in power supply by-passing to eliminate unwanted coupling of circuits that result in both propagation of spurious signals directly and paths of regeneration.
One of the advantages of ham-band-only receivers is that frequency ranges which will have a lot of spurious signals, so called "forbidden" zones, can be conveniently placed in the "deaf" range of the receiver. Can't be done for general coverage so the design becomes much more difficult.

You can also take the frequency of the birdie and see if it relates to any product of the VFO and het oscillators

5468. Question re: C-Line interconnect cables

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-06-13 03:05:32 UTC
From: dean_k5dh
Topic: 5468 Message: 5468

Hi all,

It's been many years since I've owned a C-Line, and now I'm putting one together. I have two questions regarding the interconnections between the T-4XC and R-4C:

(1) The T-4XC manual instructs the reader to use "low-capacity" coax cables for the Injection and Carrier Oscillator connections. What type of coax is that? I seem to recall that it was RG-62/U, but I may be wrong.

(2) For the Mute, Anti-VOX, and PTO Lamp connections, can I use audio-type shielded cables, since those are not RF connections?

Thanks and 73,
Dean K5DH

Yes, RG-62.

>
> (2) For the Mute, Anti-VOX, and PTO Lamp connections, can I use audio-type shielded cables, since those are not RF connections?

Yes, inexpensive stereo interconnecting cables work fine for Anti-VOX, PTO, and Mute. These circuit have audio and low level DC voltages flowing through them, not RF.

Dale,

Yes, you said you connected to the 50 ohm dummy load but did you remove the coax and connect a 50 ohm resistor across the antenna terminals? If not do that then let us know what the results are.

You need to eliminate all possible components at the antenna connection to determine what is causing the birdie problem.

Hi Dean,

The RG-62 I use is about a foot long. I have the T4XC and R4C next to each other. If your setup has the MS-4 between the transmitter and receiver then you could make the cable 2 feet long. That is about the longest I would make it, 2 feet (24 inches).

I would use good quality metal RCA plugs and not use those cheap plastic wide RCA plugs. For one reason, the RCA sockets on the rear of the receiver are very close together and those wide cheap plastic RCA plugs are difficult in insert once you have the other cables plugged into their appropriate sockets and that includes the antenna and speaker connections (antenna and speaker are right next to each other).

If you are going to operate transceiver then I recommend reading up on this method of operation in the operators manuals.

From: Michael
Topic: 5473 Message: 5473

Complete station. R-4C with all three Drake crystal filters, Sherwood custom front panel switch for the USB/LSB CF-2K/8 filter pair, Sherwood CF-600/6 first IF roofing filter, three ten meter crystals, super clean and ready to go. T-4XC in similar condition, full output. AC-4 working good with AC-4R rebuild kit still sealed (never got around to putting it in); MS-4 speaker; original Drake cables with new Lo-Loss PTO and INJ cables; all recently serviced and tweaked by Gary Poland, W8PU. Hi-Res detailed photos at < http://s272.photobucket.com/albums/jj167/wa0epw/?start=all >. I have over $1,500 invested in this station and will consider offers of $900 or better plus packing/shipping from St. Paul MN. Contact off-list at ctrpoint2004(a)yahoo.com . Thank you & 73. had to build a pair for the halli SX117/HT44 twins . don't remember what length is , hallicrafter has the specific length stated in the manual. I had to do some searching for these and don't remember wher I finally located them , probably mouser or allies electroinics . try mouser first . I used right angle 90 deg. shielded phono plugs . makes a much neater as well as easier hookup and you don't have to bend the cable .

From: Garey Barrell
Topic: 5468 Message: 5475

Dean -

All original cables were 38" long tip-to-tip.

The INJ, (and CAR OSC in the C-Line, cables used a foam inner dielectric and phono connectors with a white insulation. This cable measures 60 pF total capacity.

All other cables used the standard for the day clear polyethelene inner dielectric and phenolic (brown) insulated phono connectors and measure ~100 pF.

Original Drake INJ and CAR OSC Cables = 19 pF/ft = .160" o.d. (foam poly)

RG-62 = 93R = 13.5 pF/ft = 0.240" o.d.
RG-59 = 75R = 14.8 pF/ft = 0.242" o.d.
RG-6 = 75R = 16.2 pF/ft = 0.270" o.d.
RG-174= 50R = 30.8 pF/ft = 0.110" o.d.
Mic Cable (Belden 8410) = Hi-Z = 33 pf/ft = 0.160" o.d. (foam poly)
Mic Cable (Belden 8421) = Hi-Z = 16 pf/ft = 0.180" o.d. (foam poly)
R/S Audio Patch Cable = 28 pF/ft = 0.165" o.d. (poly)

The best choice is the Belden 8421 Audio cable from their "Brilliance" line. It looks just like the other cables, and is very flexible. The RG-62 is OK, but it is 50% larger and far less flexible. RG-62 is also prone to shorting if bent over too small a radius, and is susceptible to heat damage when soldering connectors. The best "feature" of RG-62 is that it is often FREE, since there have been many miles of it pulled out of old computer networks. Belden 8421 is available by the foot from ACK Electronics in Atlanta. Other distributors have it as well, although many require purchase of a full spool.

(Hi all, I still have some of the Belden 8421 cable left. I sell it for 10 cents an inch or $1.20 a
foot plus shipping vis USPS from Payson, Arizona, 85541, USA. Please email me (directly if you are
interested.
(
(Al, n7ioh

The only pertinent factor is the total capacity. Impedance and "loss" are not important.

Any _reasonably low capacity_ coax will work if the units are cabled together for the adjustment of the INJ trimmers.

The cable type ONLY affects the LEVEL of the PreMix signal, (5.645 MHz ABOVE the transmit/receive frequency,) and a small DC control voltage between the two. If the shunt capacity is too high, insufficient LO

level for the first mixer will reduce the sensitivity of the receiver
and the output power of the transmitter.

Some of the "commercial" cable mfrs use RG-59A, but it's a little larger and also prone to shorting
if bent over too tight a radius.

The ANT lead to the receiver is too short to matter, but you want good shield integrity, which
usually eliminates R/S cables.

The best connectors I've found are the Switchcraft 3502 plugs, available from just about anyone,
Digikey, Mouser, Allied, Newark and just about any reputable parts place.

I bought a box of drake parts, seems they are for the r4c, or mostly.
Found two filters in there marked :

Heath dynamics 5645-8 My r4c says Piezo filter, is this the same 1 st if filter for the R4C or an aftermarket 8 pole? Any ideas?
Cant find any info on it...

If it is, could I put it in my spr 4, think its a better filter but dont know about the impedences.

Any ideas?

Thanks,
Ed W1FU

Hello Ed,
The SPR-4 crystal filter is square and has an impedance of 1200 ohms. The R-4C 1st IF is 900 ohms and the 2nd IF is 50 ohms and filters are rectangular.

Date: 2011-06-15 22:44:47 UTC
From: w4rl@bellsouth.net
Topic: 5479 Message: 5479

Fellas,

What would keep the K2 relay in a Drake TR-4C from not energizing. My TR-4C had been stored inside a closet for about a year and I put it back on line in the shack. The relay worked for a while then quit. I get plate resonance or what I think is such still but no peaks on mic gain increase.

Thanks

Robert W4RL

Robert -

Relay R2 in the TR-4 is energized ONLY in X-CW and X-AM modes. It does NOT energize in either CAL
or SSB.

Are you able to set the IDLE current on the PA?

Is there RF output in X-CW (TUNE) mode?

Gary
Whilst we are on the subject of relays I have a similar problem with my 4XC. It has suddenly stopped keying (CW). I get full output on 'tune' and the correct idling current. I can also hear the relay latching in but no output when keying - even with the gain at max. The controls are at LSB - x and x-cw.
Any ideas before I open it up, please?

Vic -

Do you get output in X-AM? Low power, 10-20W.

If you DO NOT, check in CW MODE for 0-1.5 VDC varied by the GAIN control on the coax lead to T14
(back in the CO compartment).

If you DO, check R104, 105 and 106 and associated contacts on switch section S1D(r).

Have an original MN-2000 manual, includes the QC tag stapled to the inside front cover. Will ship it for $15 to your mailbox, lower 48 states only, not Alaska, Hawaii, or foreign countries.

73,

Evan, K9SQG

Robert -

Relay R2 in the TR-4 is energized ONLY in X-CW and X-AM modes. It does NOT energize in
either CAL
or SSB.

Are you able to set the IDLE current on the PA?

Is there RF output in X-CW (TUNE) mode?

Drake seems to have done will with its mechanical design and components. I don't have nearly the experienc on it of others but have found that mostly its electrolytics that go bad (as would be expected). Other caps usually are OK. I've changed some because I was trouble shooting but they did not need to be changed. Drake seems to have good good quality composition resistors. Again, I've found some that were way off value but mostly in expected locations and not enough to shotgun them.
From the standpoint of performance the Drake construction technique works very well, very short leads, etc. That makes it hard to work on but considering the age of this stuff and that much of it has been neglected in various ways, it doesn't need a lot of work.
Collins approach to construction was, I think, generated by their history of making aeronautical and military equipment. I also think they had some innovative circuit designers but ham radio seems to have been definitely a secondary market to them especially after WW-2.

There were other manufacturers after about 1950 with innovative design but few seemed to have the combination of good performance, good value, and business acumen that Drake did. Hallicrafters is a curious case, they were the only one of the big three (National and Hammarlund being the others) who seems to have caught on to the SSB movement early but I think were so oriented to semi-consumer equipment and having too many bells and whistles that their no question innovative designs in many cases simply were not executed well. Nonetheless some H equipment is still highly desirable. Hammarlund and National do not seem to have weathered re-conversion well at all. National eventually came up with some very advanced receivers but too late to give them a footing in the market. Drake stuff had the right combination of performance, affordable price, and _usable_ features that made it successful and still a contender among much newer equipment.

Hi Garey,

After reading your response, I gather that the most important thing is to end up with a cable assembly that's about 60 pF total. You recommend Belden 8421, whose capacitance is 16 pF per foot, or 1.333333 pF per inch. That means the cable ass'y would have to be 45 inches long to yield 60 pF. Is that right, or are my math skills failing me? To reach from the TX to the RX, the cable only needs to be about 16 inches long. I guess I could roll up and zip-tie the 45 inch cables and and tuck them behind the station, but that's messy.

If the important thing is to end up with 60 pF, then why couldn't I use 23.4 inches of RG-174? If my calcs are correct, that should yield about 60 pF. You stated that the impedance of the cable doesn't matter. RG-174 is plenty flexible, I've had good success at soldering it without melting the center dielectric, and I have a bunch of it in my cable stash.

I know we should probably be having this discussion via private e-mail, but I'm hoping others will benefit from it also.

Dean -

I wasn't quite clear enough! :-)

The 60 pF figure should be taken as a maximum. It is essentially 'across' the output of the PreMixer of the driving unit, so acts as a bypass capacitor, ergo, the less the better. A 60 pf
cable looks like a 470 ohm load, while the 100 pF would be 280 ohms. Obviously Drake had no way to
know which receiver would be used with which transmitter, so they just adjusted all units to work
with the 60 pF cable they supplied. This is also the reason why it's best to peak the INJ trimmers
with the two units connected together.

The 60 pf specified in my note is end-to-end, _including_ the capacitance of the RCA phono plugs
on each end. This would imply that the plugs were about 6 pF each, but I've never measured just the
connector! Years ago I just measured the capacitance of a Drake INJ cable on a bridge.

The rest of the cables were all 'three foot' patch cables and had phenolic insulators in the
connectors. The INJ cable was made to be the same length as the others, and had a clear or white
insulator in the connectors, probably polystyrene back then.

So bottom line is, keep the total cable capacity as low as feasible, and touch up the INJ trimmers
on both units with the cable installed.

Hey Garey,

Thanks for the clarification. The bottom line now seems to be: (1) the less capacitance, the better, and (2) tweak the injection trimmers in the TX and RX no matter what. So, it sounds like if I obtain some Belden 8421 and some good quality RCA plugs, make the jumpers physically short (just long enough to do the job), and then tweak the trimmers, I should be in good shape. Am I on the right track now? :)

5490. 4-Line PTO Range

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-06-18 01:18:53 UTC
From: Darrell Bellerive
Topic: 5490 Message: 5490

What was the range of the 4-line PTO?

The specs list 500 kHz, but I wonder if one could tune a few kHz above or below this range? I know my Heathkit SB-101 would go 10 to 15 kHz more on each end of the LMO than the 500 kHz spec.

73,
Darrell Bellerive

Dean -

You got it. Don't make the cable too short. There is nothing wrong with 36" of 8421, and short
cables lead to strain on connector terminations when gear is moved around!!

> Hey Garey,
>
> Thanks for the clarification. The bottom line now seems to be: (1) the less capacitance, the better, and (2) tweak the injection trimmers in the TX and RX no matter what. So, it sounds like if I obtain some Belden 8421 and some good quality RCA plugs, make the jumpers physically short (just long enough to do the job), and then tweak the trimmers, I should be in good shape. Am I on the right track now? :)

>>> Hi Garey,
>>>
>>> After reading your response, I gather that the most important thing is to end up with a cable assembly that's about 60 pF total. You recommend Belden 8421, whose capacitance is 16 pF per foot, or 1.333333 pF per inch. That means the cable ass'y would have to be 45 inches long to yield 60 pF. Is that right, or are my math skills failing me? To reach from the TX to the RX, the cable only needs to be about 16 inches long. I guess I could roll up and zip-tie the 45 inch cables and and tuck them behind the station, but that's messy.
>>>
>>> If the important thing is to end up with 60 pF, then why couldn't I use 23.4 inches of RG-174? If my calcs are correct, that should yield about 60 pF. You stated that the impedance of the cable doesn't matter. RG-174 is plenty flexible, I've had good success at soldering it without melting the center dielectric, and I have a bunch of it in my cable stash.

Darrell -

The Drake PTOs will go at least 100 kHz extra on either end. I've never checked the linearity in
those regions, but they'll easily go that far.

Yes and no.

The crystals WILL 'work', but will be 10 kHz off frequency. Crystals for the other receivers in the
4-Line all use a crystal 11.1 MHz above the bottom end of the desired coverage, e.g., to cover from
3.0 to 3.5 MHz takes a crystal at 14.1 MHz. In the SPR-4, coverage of this same range takes a
crystal at 14.09 MHz.

Gary -

Yes, I believe you're correct, it uses HC-49s I think. So you'd also need some sort of adapter.

Ok for experimental use, but new crystals seem a better choice.

5498. TR-4 Redux

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-06-22 21:36:33 UTC
From: Richard Knoppow
Topic: 5498 Message: 5498

This is being posted to both Drake lists. Some time ago I wrote asking some questions about a TR-4 I had just aquired. While in generally very good condition it had some problems, a couple of which were puzzling. I pretty much found the solutions to all and have the rig working very well now. Much thanks are due to Garey Barrell who is not only a fount of knowledge but a very patient person:-)

Problems and solutions:
No signals on the three ten meter bands.
This turned out to be a very persistent oxidized section of the band switch. I found that the problem was cured by dosing it with contact cleaner but the next day it would be back again. Beside cleaning the contacts I also re-flowed the solder joints around the switch but it seems to have been oxidation mainly. I am still not sure I have a permanent cure but what I did was to scrub the rotor with contact cleaner using a soft wooden stick. This was an extra-large toothpick of the sort used to hold sandwiches together but a wooden match stick would do. After scrubbing I applied a small amount of General Cement Tuner Lub. I've had goog results with this in the past for salvaging persistently intermittant rotary switches. Well, it seems to be working, I will report later on whether it continues to keep the switch working.
Another annoying problem was a feedback when adjusting the RF tuning for receive. This came from a signal emmitted by the AM detector/side tone generator tube. Garey suggested bad by-pass caps but I tried bridging the caps with new ones and there was no change. I cured the problem by shielding the tube. I used a push-on type shield which is grounded by the two screw ends sticking up next to the socket. No modification needed. It works perfectly and completely eliminated the feedback. I note here that I did not actually replace the caps because they are packed in tight, _no_ leads whatever. Also, the originals are ceramic discs, unlikely to have gone bad.
Low power output. That was just bad final tubes. They would make about 60 watts on 80 meters. I had some spares for my T-4XB and got some additional ones from my tube source. I also made up an adaptor socket for my TV-7B tube tester and checked all of my 6JB6 tubes on it. This allowed me to cull out the bad ones and to get a set of tubes with a reasonable match. After installing the new set the power went up to around 180 watts on 80 and over 100 on 10 meters.

The tubes neutralized easily even though they are mixed brands.
The adaptor is simple to make. I was able to get the necesssary sockets and plugs from my tube guy. Total cost of this adaptor was probably a dollar.
I managed to zap the "fuse" lamp in the antenna circuit and had to get new ones from the internet. They are No.12 lamps, same rating as a No.47 but are in small envelopes with a stem seal base. I found after putting the new one in that is was intermittant. Cured that by cleaning the lamp contacts, squeezing the socket contacts, applying Deoxit and as with the switch Tuner-Lub. It now seems to be solid.
I can't think of any other major problems. I did a complete alignment and that brought up the receiver sensitivity to spec where it was a bit low. The specs say that the meter should read S-9 from about 30 uV. While this is hardly a precision measurement I was getting about S-7 before aligning. It now reads correctly.
Bouncing meters. Both meters bounce. I tried shorting right across the meter terminals (with the power off of course), the meters still bounced. That says they are cheap meters without strong enough magnets to damp them properly. Good meters will be sluggish when shorted. Garey says this is a common problem and that some users have had luck putting capacitors across the terminals. I will try that in the future but the fact that the meters have poor damping when shorted makes me think the caps would not cure the problem. Its annoying because it makes it difficult to tune the plate quickly.
I am at the moment without an antenna, very frustrating but I can check the receiver part using a makeshift antenna (not good enough for transmitting) and check the tansmitter using a dummy load and second receiver. The quality of both is excellent. This is a very good little SSB rig. I don't much like its AM quality either transmitting or receiving. Its acceptable for CW but the selectivity of the RX is insufficient for regular use.
One other thing, the blue filters in the dials were not the correct gel. When dimmed the dials became unreadable and were pretty dim even with the dial lamps at full brightness. I took the filters out and will eventually replace them with the correct Lee gelatins.
I also had to replace the neon VFO indicator lamp. These get weak with age. The one I took out was almost black inside. I was able to get exact replacements from Newark supply. They are very cheap. I thought I was ordering five lamps and wound up with five _boxes_ of lamps. They are not hard to change although it does require removing the front panel. Probably has to be done every twenty years or so:-)
I hope any of this is helpful to someone else.

5499. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-06-26 19:09:04 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5499

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

5500. New member and request for help

Hi,

I've recently acquired an early model TR-4 (1965 vintage) which requires a lot of TLC to bring it back into use, so decided to join the Group and make use of the knowledge base. Have previously owned 2-B and 2-C receivers which were great performers.

Can anyone help answer the following TR-4 questions please?
- does the early (original?) model TR-4 (6HS6 tx mixer) schematic or manual differ much from the 1966 version (6EJ7 tx mixer) - I only have a copy of the latter. If anyone can provide a copy of the early version that would be great!
- I don't have an AC-4 psu, but I do have a Heathkit HP23B psu - I have read that this can be used (outboard bias pot required) but is the higher B+ (800V) of the HP23B a problem?

Thanks in advance for any help.

Roger

Roger,
I would think that the differences between the schematics would be considerable between those. I recommend Garey Barrel's CD's on the Drake gear to work on any of them. Contains not only all the schematics, but good parts placements pictures in color that are VERY valuable when working on these. Contact Garey at k4oah@... for details. I wouldn't use the Heathkit power supply on the Drakes, as the high voltage was designed for the 6146's, not our 6JB6's. I think it would stress them greatly.
73 and welcome to the group,
Don, WB5HAK

Roger -

Yes, there are several differences between Version 1, and the next seven versions of the TR-4. I
have sent you a copy of the correct schematic directly as the list doesn't permit attachments.

I've never tried using an HP-23 supply, but the AC-4 supplies 700 VDC at no load. That voltage is
only applied to the PA stage, and the components in the path should be able to withstand that
voltage. You wouldn't load quite as high in PLATE current, but the mismatch should be within the
limits of the Pi-Net to match. As you say, the BIAS must be made adjustable.

5509. Re: install sherwood mods on R4C

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-07-05 16:17:29 UTC
From: w5rkl
Topic: 5505 Message: 5509

Hi Dale,

I responded to your questions yesterday evening but it appears my response didn't make it for what ever reason.

I have a 20K serial number R4C that I have installed the following Mods and Filters

Sherwood Mods:

1. Power supply
2. Filter capacitor board FC-4. This was before Heyseedhamfest.com marketed their R4C capacitor kit.
3. 3rd Mixer (MIX-4)
4. AMP-4 audio amplifier

INRAD Filters:

1. 6Khz AM filter
2. 500Hz and 250Hz CW filters
3. 6Khz GUF-1 first IF filter
4. 1.8Khz SSB filter

Installing the Sherwood modes was rather easy. The only mod that required drilling was the GUF-1 since INRAD's GUF-1 filters are physically smaller than the larger factory Drake filter. A template comes with the GUF-1 filters for drilling the mounting and input/output pin holes.

The Sherwood power supply requires soldering a 1/2" copper strap to the side wall of the R4C chassis. A large wattage soldering pencil is required to do attach the copper strap to the side wall of the R4C's chassis. The instructions are complete and easy to follow. No guessing as to how the wires are to be connected.

The 3rd mixer requires removing the 3rd mixer tube, a 6EJ7 in my R4C, then making a couple of wiring changes, then connect the mixer. The tube socket remains "empty", no tube installed.

The audio amp, AMP-4 is easy to install. The wiring to the audio transistor on top of the R4C chassis, between the LMO and the power transformer, is removed/disconnected. The AMP-4 PC board is mounted directly behind the front panel, next to the audio gain and phone socket. Instructions are provided with a picture of how the AMP-4 board is installed. Easy to install, about 30 minutes for me.

Depending on which R4C you have (3 or 5 position MODE switch settings) determines where the AM filter is installed. In the 3 position MODE switch R4C the AM filter is installed on the rear panel while the 5 position MODE switch, the AM filter is installed inside the R4C, on the left side of the rear bracket.

The SSB and CW filters install on the rear panel, even with the 5 position MODE switch position R4C.

As for improvements, the Sherwood power supply significantly reduces the heat produced in the R4C, regardless what version R4C you have.

The AMP-4 audio amplifier has a nice frequency response, not a "tinny" sound. The IC chip is an LM-383, the older version of the current TDA-2003 7 watt audio chip. The AMP-4 will produce over 2 watts of audio without distortion.

The 3rd mixer is suppose to eliminate 3rd mixer noise. I can't say I did a "before" and "after" comparison but it works rather well.

Before you install any mods and filters from Sherwood and INRAD, I would ensure the alignment of your R4C is correct (see the R4C manual for alignment instructions). If any tubes are gassy then the alignment, for example, of the S meter will not align properly. Therefore, if you suspect any tubes may be gassy, replace them before you attempt aligning the R4C. You can tell if a tube is gassy by measuring the tube's grid voltage on each side of the grid resistor. If the grid voltage is more positive on the grid side of the resistor than on the opposite side of the grid resistor then the tube is most likely gassy. I checked the alignment of my R4C before installing any mods and filters. I was lucky, the alignment was very close to the factory alignment, I only needed to tweak a few adjustments to bring the R4C into the factory alignment.

I like the way my R4C performs after installing the mods and filters. The 250Hz CW filter does not ring. When using the 500Hz and 250Hz CW filter along with the Notch and Passband controls, elimination or significantly reducing adjacent frequency interference is greatly improved. The 6Khz AM filter does an excellent job on AM. You will see a significant difference in AM operation by installing the AM filter instead of the resistor across the filter terminals.

The draw back is the overall cost. The 4 INRAD filters will cost you approximately $650 plus shipping (current INRAD prices). The Sherwood mods will cost approximately $160 for a total of $818 plus shipping cost. Sherwood charges $20 shipping (see the Sherwood site for full shipping cost details).

Another thing you should consider and that is, if you do not plan on keeping your R4C then spending $818 plus shipping cost for the mods and filters may not be worth it to you. I still have and continually use my R4C and have no plans on selling my modified R4C. I paid $100 for my R4C at the Friedrichshafen, Germany hamfest back several years ago, I was working for General Dynamics in Vaihengen Germany near Stuttgart at the time.

I hope this helps answer you questions about the Sherwood and INRAD filter mods.

5510. TR-4C carrier balance

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-07-05 16:40:50 UTC
From: w1kilofoxtrot
Topic: 5510 Message: 5510

Well, carrier balance would be a mis-nomer, since it does not appear to balance at all. My SSB signal (into a dummy load) is rather more like AM. I suspect the diodes in the TX mixer (T14?) may be bad, but as it looks like a pain in the rump to chase down, I thought I'd ask the collective if there's something else I might have missed.

Any thoughts as to anything else I should run to ground first??

Dale,

In my recent response I said the cost of "4" filters was approximately $650. The "4" is wrong. The $650 is for "5" filters, SSB, AM, 2 x CW (500hz and 250hz), and the GUF-1 filter, hence "5" filters, not "4".

A couple of questions: Does the balance control have any
effect at all, and does the balance capacitor have any
effect? The latter might not if the balance is way off. I
think the only way to determine if the diodes are bad is to
measure them.
If you have a two channel scope you can look at the
drive to the diodes with one channel inverted, that will
tell you if the drive to the diodes is balanced.

Thanks for the idea to look at the two inputs, could eliminate the pot as a possible. There was no discernible effect going 10 turns on the pot, so did not even bother with the cap.

Will try looking at that, and see what I find!

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-07-05 18:33:49 UTC
From: Garey Barrell
Topic: 5510 Message: 5514

Steve -

You can do an ohmmeter check, preferably the DIODE TEST function of a DMM. With the FUNCTION switch
in the CAL position, power off, measure from the terminal of T14 with the center lead of the
shielded lead connected to it to chassis. ?With a DMM you should read TWO diode drops (about 0.7 V
for two Germanium diodes) in either direction (polarity). With an ohmmeter, you should see approximately the same low resistance either way. Hard to say what is correct, since it depends
upon the ohmmeter circuit and battery voltage, etc. The key is that it should read the same EITHER way.

These diodes have been known to develop a short to the can, in which case you only see ONE diode
drop (~0.35V). Of course if a diode is open or shorted (VERY unusual) your meter should read
accordingly.

I should have suggested testing the pot and the build
out resistors first using an ohm meter. If the pot is bad or
one of the resistors has gone open or has changed value
substantially, that is your problem. The RF test is useful
if all the resistors look good.
I am not sure how the diodes are mounted in the TR-4C,
in my T-4XB and TR-4 the diode bride is mounted inside the
can with the transformer. Its easy to get off by compressing
the spring catches at the sides. Once off you can check the
diodes and see if there is anything that might be shorting
to the can. I think its ver unlikely that the diodes are bad
but there may be a short or perhaps a cold solder joint.
Check the resistors with an ohm meter first. I don't
know why I didn't include that in my first post.
I had a struggle with my T-4XB due to what turned out to
be a wiring error probably made by a former owner. The
wiring _looked_ fine and I chanced all around Robin Hood's
barn trying to find the reason the modulator would not
balance correctly. Finally I got Garey Barrell's service
disc and noticed that the photograph of the area with the
modulator looked a little different. Garey checked one of
his units for me and sure enough the two leads to the
modulator were interchanged. This had enough effect on the
stray capacitances to prevent getting a good null. In the
meantime I had replaced good parts and wasted a lot of time.
OTOH, I got a liberal education on this Drake rig.

Thanks to both Richard and Garey. It turned out to be a bad solder joint. With that fixed, I trimmed the pot and cap, and have set the balance to an acceptably low level. It's on the order of 50 uV on the output of the following IF amp.

On to the next issue!

(At last the knobs look good; I cleaned them and repainted the white lines...)

This is what I learned the hard way! Drake used good quality components and had excellent designs. There is not much that can fail in them but, they are getting old so some problems that happen due to long time stess occur. Crystalized solder joints are among them.
It would be interesting to know what sort of soldering equipment was used at the factory. The components are packed in very tightly and many have virtually no leads. This is good from an electrical standpoint but must have made manufacture difficult. Also, Drake seems to have used wire with insulation that melts with a passionate look from warm brown eyes. So I am curious about how they went about assembly.

Mike
thanks for the one and only explanation of the Sherwood mods from anyone. I figured lots of guys would respond with glowing reports of the mods,but nothing ever showed up. I haven't gotten the R4C yet,should be here on thursday. I will go thru a alignment before starting the mods as you suggested. I have had 2 drake 4 lines over the years,a 4 and a 4B both were very good. I guess I was curious when the C line became aviable and decided I would go for the whole thing. I have the GU-1 filter,will order the mods tomorrow . I have stock filters for the rig so will live with them for a while. I do little cw any longer so It will be ssb with the C mostlt. Thanks for the time to answer my questions ,sure makes the project much more understandable.

Subject: [DrakeRadio] Re: install sherwood mods on R4C

Hi Dale,

I responded to your questions yesterday evening but it appears my response didn't make it for what ever reason.

I have a 20K serial number R4C that I have installed the following Mods and Filters

Sherwood Mods:

1. Power supply
2. Filter capacitor board FC-4. This was before Heyseedhamfest.com marketed their R4C capacitor kit.
3. 3rd Mixer (MIX-4)
4. AMP-4 audio amplifier

INRAD Filters:

1. 6Khz AM filter
2. 500Hz and 250Hz CW filters
3. 6Khz GUF-1 first IF filter
4. 1.8Khz SSB filter

Installing the Sherwood modes was rather easy. The only mod that required drilling was the GUF-1 since INRAD's GUF-1 filters are physically smaller than the larger factory Drake filter. A template comes with the GUF-1 filters for drilling the mounting and input/output pin holes.

The Sherwood power supply requires soldering a 1/2" copper strap to the side wall of the R4C chassis. A large wattage soldering pencil is required to do attach the copper strap to

the side wall of the R4C's chassis. The instructions are complete and easy to follow. No guessing as to how the wires are to be connected.

The 3rd mixer requires removing the 3rd mixer tube, a 6EJ7 in my R4C, then making a couple of wiring changes, then connect the mixer. The tube socket remains "empty", no tube installed.

The audio amp, AMP-4 is easy to install. The wiring to the audio transistor on top of the R4C chassis, between the LMO and the power transformer, is removed/disconnected. The AMP-4 PC board is mounted directly behind the front panel, next to the audio gain and phone socket. Instructions are provided with a picture of how the AMP-4 board is installed. Easy to install, about 30 minutes for me.

Depending on which R4C you have (3 or 5 position MODE switch settings) determines where the AM filter is installed. In the 3 position MODE switch R4C the AM filter is installed on the rear panel while the 5 position MODE switch, the AM filter is installed inside the R4C, on the left side of the rear bracket.

The SSB and CW filters install on the rear panel, even with the 5 position MODE switch position R4C.

As for improvements, the Sherwood power supply significantly reduces the heat produced in the R4C, regardless what version R4C you have.

The AMP-4 audio amplifier has a nice frequency response, not a "tinny" sound. The IC chip is an LM-383, the older version of the current TDA-2003 7 watt audio chip. The AMP-4 will produce over 2 watts of audio without distortion.

The 3rd mixer is suppose to eliminate 3rd mixer noise. I can't say I did a "before" and "after" comparison but it works rather well.

Before you install any mods and filters from Sherwood and INRAD, I would ensure the alignment of your R4C is correct (see the R4C manual for alignment instructions). If any tubes are gassy then the alignment, for example, of the S meter will not align properly. Therefore, if you suspect any tubes may be gassy, replace them before you attempt aligning the R4C. You can tell if a tube is gassy by measuring the tube's grid voltage on each side of the grid resistor. If the grid voltage is more positive on the grid side of the resistor than on the opposite side of the grid resistor then the tube is most likely gassy. I checked the alignment of my R4C before installing any mods and filters. I was lucky, the alignment was very close to the factory alignment, I only needed to tweak a few adjustments to bring the R4C into the factory alignment.

I like the way my R4C performs after installing the mods and filters. The 250Hz CW filter does not ring. When using the 500Hz and 250Hz CW filter along with the Notch and Passband controls, elimination or significantly reducing adjacent frequency interference is greatly improved. The 6Khz AM filter does an excellent job on AM. You will see a significant difference in AM operation by installing the AM filter instead of the resistor across the filter terminals.

The draw back is the overall cost. The 4 INRAD filters will cost you approximately $650 plus shipping (current INRAD prices). The Sherwood mods will cost approximately $160 for a total of $818 plus shipping cost. Sherwood charges $20 shipping (see the Sherwood site for full shipping cost details).

Another thing you should consider and that is, if you do not plan on keeping your R4C then spending $818 plus shipping cost for the mods and filters may not be worth it to you. I still have and continually use my R4C and have no plans on selling my modified R4C. I paid $100 for my R4C at the Friedrichshafen, Germany hamfest back several years ago, I was working for General Dynamics in Vaihengen Germany near Stuttgart at the time.

I hope this helps answer you questions about the Sherwood and INRAD filter mods.

Good evening Dale,

I was reading the thread with great interest. I had never summed up the Sherwood mods, but now understand your statement that you expected the MODS for the price that I was asking for the stock C-line. Had the twins and pwr suply been with mods it would have been a bargain at $1k.

More interesting was the sparse commentary on the MODS. I wonder just how good the human ear is to note the difference. Perhaps all of those who modified are not on the net, or perhaps the MOD do not glow. The sum is a substantial investment.

It is all great fun no matter what. I switch from my R-4 to the R-4c to the TR-4C to the TR4-CWx and combinations of them. My finding is that the R-4any is a better listening rig than the TR-4any - more control of bandwidth, notch and audio.

Dale,
I don't really mean for this to sound ;negative at all, but one thing that hasn't been said in all this string is that you should use the C line at least some before you begin the mods. It is a fine set in its own right without doing anything but routine maintenance. Sure the Drake engineers had to watch nickles and dimes in its production, but for most casual use (non contest in a "critical" environment), it will soar compared with most rigs. Besides, if you don't, you won't know if you got your money's worth, hi.

Yes, there is enough mixer noise that I MAY put that mod in one day, and I MAY consider the audio board replacement (not necessarily Sherwood) at some point, BUT it is a tube rig, tube rigs get hot, and we do have fans, so maybe not. To each his own, but when I'm using the B line, C line, Johnson Viking II, KWM-2A, and on and on, I'm looking for that mellow sound that I miss in the new rigs I have. When I want to "dig out the last DX weak station", I go to the IC-7700 or FTDX9000. That's just me.

Enjoy those Drakes!!!!

Hear hear, Don !!!!! Right on. I started to say about the same thing and then dumped my message. It always amazes me why someone not knowing anything about a radio immediately wants to do mods. Just crazy as far as I am concerned. That is like buying a model T FORD and then immediately adding power steering, automatic transmission, satellite radio, and automatic turn signals, and digital dash board. Sure this stuff is better then what Ford put into their car. However, you don’t experience the car as it was doing this sort of stuff. I enjoy using my Drake gear as Drake engineered and built it. I use my new modern radios when I want those newer features. Drake equipment, as is, is wonderful left alone. I don’t want any cobbled up rig in my shack. But then, those are my personal views.

I have owned a 4 line and a B-line for over 10 years,just recently selling both. I think that gives me a pretty good sense of what the drake C line should be able to do. If the problem with the C line ,if any, shows up and looks like it could be helped with the proper mod ,will give it a try,if not like they say if it ain't broke, then don't fix it. I was calling for some input about the mods for the C, to see what others had to say about the mods. Not knowing anything about the radio,kind of a untrue statement in this case,but what the hell,should be a fun adventure.

Dale,

You are using good judgment. The C line is one fine radio as stock. Give it a try that way. You will be pleased. As for the mods, there are many more Drake C line radios out there without mods then with them. I think that says something. After using your C line, you can decide if you want to modify it. There is a mod to solid state the audio output as it produces less heat. There are filter mods as well. Yes sometimes old filters will go bad or drift off frequency and it is good to replace them. But, you can go crazy with filters which I find to be crazy unless you are a top 100 contester in the world. For the average ham or even for most over average, the stock filter arrangement is just fine. Some like the “sound of the “B” line better then the “C” line. That is because the crystal filters in the “C” line are sharper and roll off faster. (You can’t have your cake and eat it too). In closing, the “C” line radio is one great radio as is. Why spend a bunch of money on something which is not needed or helpful to most owners. In my estimation, a modified Drake is no longer a Drake. You need to decide for yourself if you indeed need or want these mods once you have a baseline understanding of the radio.

There are two types of guys on this list. There is a following for these mods and they will violently disagree with me. That’s their choice as many others feel as I do about all this. Some of us are not top 100 contesters and want to experience radios as they were built. We don’t want any part of modified radios unless the mods can allow us to continue to use an otherwise unusable radio or the changes are not drastic. Many of us have current production gear besides our Drake or other vintage equipment. We use these pieces to satisfy our “state of the art” desires. I too have a B line as well as some C line equipment. I much prefer my C line equipment. Some on here prefer their B line equipment. For them, it usually comes down to how the radio ‘sounds” or the radio doesn’t need accessory crystal filters. It’s best for you to decide what you like or dislike about a radio and not take someone else’s word for it.

Hi Lee,

Of course, there are different degrees of acceptable modification. While I do not hesitate to add a truly "value added" mod, I would not go so far as to deface the outer cosmetics to get there. For example, I would not consider adding extra indicators, switches, controls, etc. God knows I've modified (and some will argue, "mutilated") the insides of my Drake receivers. There are probably enough unmodified R4x receivers that the few that are modified will not affect the preservation of Drake history.

Some Drakes will forever stay pristine. Great. Their owners want to keep them that way. But, there are also users who would like the aptitude and acumen to be able to go in to their Drakes, service them and even change circuitry. They would like to, but don't know how, absent sending it off for the work to be done. But labor costs can quickly undermine the value of having the modifications when it's time to sell the gear.

Given the high demand and selling price of R-4Cs with Sherwood mods, I think some end-users can justify the increased level of performance, reduction of cabinet heating without the need for external cooling, etc. I do think that if most folks could hear, feel, and use my modified R-4B and R-4C receivers, they would think twice about keeping them historically accurate. Not all, but certainly many.

I look at modifying a Drake like I would modify a Corvette. There's no shortage of extremely expensive, vintage Corvettes that have been heavily modified for peak performance. A vintage Corvette owner may add a Monza exhaust system, but would never consider adding a useless ornament to the car body. On the other hand, I look at the Collins S/Line as something more akin to say...a Mercedes sports car where one would probably not modify it. I just acquired an S/Line and folks here can rest assured that not one item will change. To me (and folks like Rob Sherwood), Drakes are destined to be changed by their owners just like some sports cars, boats...the list can go on.

Subject: Re: [DrakeRadio] Re: install sherwood mods on R4C

Hi Lee, Of course, there are different degrees of acceptable modification. While I do not hesitate to add a truly "value added" mod, I would not go so far as to deface the outer cosmetics to get there. For example, I would not consider adding extra indicators, switches, controls, etc. God knows I've modified (and some will argue, "mutilated") the insides of my Drake receivers. There are probably enough unmodified R4x receivers that the few that are modified will not affect the preservation of Drake history. Some Drakes will forever stay pristine. Great. Their owners want to keep them that way. But, there are also users who would like the aptitude and acumen to be able to go in to their Drakes, service them and even change circuitry. They would like to, but don't know how, absent sending it off for the work to be done. But labor costs can quickly undermine the value of having the modifications when it's time to sell the gear. Given the high demand and selling price of R-4Cs with Sherwood mods, I think some end-users can justify the increased level of performance, reduction of cabinet heating without the need for external cooling, etc. I do think that if most folks could hear, feel, and use my modified R-4B and R-4C receivers, they would think twice about keeping them historically accurate. Not all, but certainly many. I look at modifying a Drake like I would modify a Corvette. There's no shortage of extremely expensive, vintage Corvettes that have been heavily modified for peak performance. A vintage Corvette owner may add a Monza exhaust system, but would never consider adding a useless ornament to the car body. On the other hand, I look at the Collins S/Line as something more akin to say...a Mercedes sports car where one would probably not modify it. I just acquired an S/Line and folks here can rest assured that not one item will change. To me (and folks like Rob Sherwood), Drakes are destined to be changed by their owners just like some sports cars, boats...the list can go on. Paul, W9AC ----- Original Message ----- From: lee To: DrakeRadio@yahoogroups.com Sent: Wednesday, July 06, 2011 1:02 PM Subject: Re: [DrakeRadio] Re: install sherwood mods on R4C Dale, You are using good judgment. The C line is one fine radio as stock. Give it a try that way. You will be pleased. As for the mods, there are many more Drake C line radios out there without mods then with them. I think that says something. After using your C line, you can decide if you want to modify it. There is a mod to solid state the audio output as it produces less heat. There are filter mods as well. Yes sometimes old filters will go bad or drift off frequency and it is good to replace them. But, you can go crazy with filters which I find to be crazy unless you are a top 100 contester in the world. For the average ham or

even for most over average, the stock filter arrangement is just fine. Some like the “sound of the “B” line better then the “C” line. That is because the crystal filters in the “C” line are sharper and roll off faster. (You can’t have your cake and eat it too). In closing, the “C” line radio is one great radio as is. Why spend a bunch of money on something which is not needed or helpful to most owners. In my estimation, a modified Drake is no longer a Drake. You need to decide for yourself if you indeed need or want these mods once you have a baseline understanding of the radio. There are two types of guys on this list. There is a following for these mods and they will violently disagree with me. That’s their choice as many others feel as I do about all this. Some of us are not top 100 contesters and want to experience radios as they were built. We don’t want any part of modified radios unless the mods can allow us to continue to use an otherwise unusable radio or the changes are not drastic. Many of us have current production gear besides our Drake or other vintage equipment. We use these pieces to satisfy our “state of the art” desires. I too have a B line as well as some C line equipment. I much prefer my C line equipment. Some on here prefer their B line equipment. For them, it usually comes down to how the radio ‘sounds” or the radio doesn’t need accessory crystal filters. It’s best for you to decide what you like or dislike about a radio and not take someone else’s word for it. Lee, w0vt Lee I have owned a 4 line and a B-line for over 10 years,just recently selling both. I think that gives me a pretty good sense of what the drake C line should be able to do. If the problem with the C line ,if any, shows up and looks like it could be helped with the proper mod ,will give it a try,if not like they say if it ain't broke, then don't fix it. I was calling for some input about the mods for the C, to see what others had to say about the mods. Not knowing anything about the radio,kind of a untrue statement in this case,but what the hell,should be a fun adventure. dale wt4t [Non-text portions of this message have been removed] [Non-text portions of this message have been removed]

I've always looked at part of being a ham is being a tinkerer, and part of that is making things better where possible. That includes well thought out and technically sound mods. There was a time when many hams spent hours tuning and tweaking to get the best possible perfomance out of their gear - an art that seems to be lost these days, judging from some of the audio I hear on the air. The notion of when it ceases to be a "Drake" doesn't bother me so much. Who's to know that some of these ideas weren't concieved by Drake's engineers, but abandoned to meet a price point? At what point does it cease to be a Drake? The ham in Eu almost completely rebuilt his TR-7, is it still a TR-7? Does a Fox-Tango 250 Hz CW filter in my Drake make it not a Drake? After all, it could be considered a "mod"... Mike Elliot worked for Heathkit, that implies that the 7-Line is at least a little bit Heath. Does that make it less a Drake? I still love my HeathDrakeFoxKit 7-Line with Japanese PA transitors and RadShack LEDs, and my lightly modded (so far) C-Line. They're still Drakes to me.

Tune 'em. tweak 'em, and use 'em.

I would like to use a single AC-4 PS on the various Drakes that I have, as I will never run them simultaneously. Was thinking of wiring the AC4 to a terminal strip and wiring individual plugs to the various radios. Might you have a better idea?

Thanks,
Ed NI6S
Los Angeles

Hi Ed,

I assume you mean that you would have three Cinch-Jones female plugs wired in parallel. I see a couple of problems with this approach.

1) One pair of wires on the cable is in series with the transformer primary and goes to the on-off switch of the radio. Turning on the power with any radio will supply power to all of the radios.

2) Since all of the radios would receive power its possible that the filament winding would not be able to supply enough current for the filaments in all of the radios.

3) Drake opted to set the negative bias for the finals using a pot in the AC-4. I have used one AC-4 to power different radios but had to adjust the transmitter idle current using the bias pot every time I switched radios.

If I wanted to use this approach I think I would build a switch box external to the AC-4. I'd modify the AC-4 to bring out the the BIAS voltage from it's source rather than the wiper of the pot. I'd install the pot and it's series resistors for each radio. I'd use a rotary switch to switch the various voltages and speaker signals to/from each of the cables to the radios.

73,

Bill

I too was a 'modder' back when I had ONE receiver, and wanted it to be the 'best I could (or could not)' make it.

My receiver in 1957 was testament to this idea. I didn't have much (any?) money so 'necessity was the mother ...' and I did what I could with what I had or could scrounge. THE receiver consisted of a BC-454 WW-II surplus unit that I paid $4.95 for brand new in the box. It was very stable mechanically and electrically (ref late 30's technology) and although the IF at 1415 kHz was at least 30 kHz wide, at least when I managed to tune in a station with my sandpapered fingers, it stayed there! One day it occurred to me that if the IF were lower in frequency, it would be more selective. I wasn't sure why, but that was the common knowledge. So my Bendix clock radio had a piece of wire wrapped into its loop antenna with the other end stuck into a hole in the top of the third IF can of the BC-454. Tuning the Bendix to 1415 kHz I ended up with a double conversion receiver with _Passband Tuning_ no less. This probably cut the IF BW in half, but still no great

shakes in the VERY crowded 80M Novice band of the late 50's.

One day I visited a local who had a Heathkit Q-Multiplier. He demonstrated it in action, and I was
smitten!! A few weeks later, after some lawn mowing income, I ordered a Q-Multiplier. The kit was
built, and I began to think about installation. I could get power from the BC-454 power supply, and
so all I had to do was arrange an IF tap in the Bendix! That was accomplished, and after blowing
two or three house fuses I got the Bendix plug in the wall the right way.

This system worked well for a while, until I saw a demo of a BC-453 receiver. This was another
surplus receiver that tuned from 190 to 550 kHz and had an 85 kHz IF. The IF transformers had a
unique feature that allowed you to adjust the bandwidth of the receiver by adjusting the amount of
coupling between the coils in the IF transformers. The 'antenna wire into the last IF can' trick
was employed once again and I had a triple conversion receiver with Q-Multiplier!!

So there can certainly be good reasons to modify a piece of equipment. I used the 1-A, 2-B, R-4,
R-4A, R-4B, R-4C, R-7 and R-8A when they were new, warts and all. I lived through the improvements
incorporated in each incarnation of essentially the same basic design, and enjoyed them all. So for
me, I prefer to use them 'au naturel', each with it's own personality, quirks and irritations. I
see no point in chopping up an R-4C when if I wanted and / or needed a contest class receiver I'd
just buy a K3! However, I'm not a contester and really don't need the superior selectivity and
performance of this or several other current transceivers. My most modern radio (aside from my 'YIG
SDR kits) is a Kenwood TS-940SAT. The '940 is superior to all the Drakes in several ways,
functionally, no tune-up required, instant band change, etc., etc., and is a pleasure to operate.
That said, being on the air with the '940 is about as interesting as using a cell phone. My feeling
is, "IF you can't dip the final, it ain't Ham Radio". Being full of tubes doesn't hurt either!

There are certainly enough 'mint' Drake units out there for the concours collectors with their
polished wafer switch wipers, bright polished IF cans, etc., so we don't really have to be concerned
about preserving 'history'. Bottom line is, it's your radio, you can do whatever you want with it.
You can do as some have, and bury it under the chicken coop for 15 years, then dig it up

and sell it
on eBay as 'mint' If you want to gut it and install a transistor radio like some have done to the
old Philco 'tombstone' and 'cathedral' radios from the 20's and 30's, have at it! MY Drakes are
going to stay just the way they were when they came off the line for as long as I can get parts for
them. :-)

Hi Ed,

I assume you mean that you would have three Cinch-Jones female plugs wired in parallel. I see a couple of problems with this approach.

1) One pair of wires on the cable is in series with the transformer primary and goes to the on-off switch of the radio. Turning on the power with any radio will supply power to all of the radios.

2) Since all of the radios would receive power its possible that the filament winding would not be able to supply enough current for the filaments in all of the radios.

3) Drake opted to set the negative bias for the finals using a pot in the AC-4. I have used one AC-4 to power different radios but had to adjust the transmitter idle current using the bias pot every time I switched radios.

If I wanted to use this approach I think I would build a switch box external to the AC-4. I'd modify the AC-4 to bring out the the BIAS voltage from it's source rather than the wiper of the pot. I'd install the pot and it's series resistors for each radio. I'd use a rotary switch to switch the various voltages and speaker signals to/from each of the cables to the radios.

I think this is one of those ideas that may not prove practical. For one thing each rig is likely to require somewhat different bias voltage. So, even though you could switch the supply from one rig to another you would probably have to set the grid bias each time.
Also, I am a believer in the idea of minimising the number of connectors and switches in a circuit. In this case there would be a lot of wiring wether a patch system or a multiple layer switch was used. I can forsee other problems. You can switch the supply from one rig to another by moving the plug but the problem of setting the bias would still remain. While its expensive to find individual supplies for each rig it may turn out to be cheaper than arranging a patch or switching arrangement capable of handling the voltages and curents involved. Also, there is a safety issue: both the high voltage and medium voltages are high enough to be dangerous so you must make sure that what ever arrangement was used can not expose you to these voltages. An AC interlock would be good. The connectors must be such that there are no male plugs with voltage on them. I think this is an idea that seems attractive but is not practical.

5540. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-07-10 19:42:03 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5540

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

Vic -

Linear. A Log or Anti-Log pot would crowd the adjustment into the first (or last) third of the
rotation.

HI to the Group and thank you for letting Me join. I am a new Drake 4-B twins owner, this is my first lot of Drake gear and All I can say is WOW Very nice ,I am just going over them to do a clean up and check the alignment , I have all manuals and Drake service CD ,Good test gear VTVM ,O'scope ,F counter etc .I have found Resistors out of spec in the T-4XB R26,R30 R31 R32 R33 & R36 Can I Use metal filament instead of carbon composite resistors ? As I have these on hand I Hope this is no A DUM Question,

Also the R-4B when I switch the AVC to fast I get A popping sound and slight distortion Is this normal ? Other than that it works and sounds very good and seams to hear as Good as my kenwood TS 830s

Thanks any replies welcome

I'm not sure if they are the best choice, but you probably mean metal FILM,
not metal FILAMENT resistors.
I suspect this is a case of "spell check strikes again".
There are also carbon film resistors.

5546. TR7 questions

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-07-11 15:10:21 UTC
From: Bob Szejk
Topic: 5546 Message: 5546

Hi, I recently bought a tr7 (early model) with only the high impedance mic input. I'm using a Turner +3 (5K output impedance). The problem is that I can't get the VOX to key the radio. If I switch the radio from PTT to VOX and key the mic, the VOX delay works fine (holds the TR7 keyed for a few seconds). But I can't get the radio to key on it's own using VOX.

Question 2 is: I have a number of mics available (D104 G-stand, Electro voice 719 high impedance ceramic, and a HEIL HM-10). I really wanted to use the HEIL, but I'm sure the impedance is too low for the TR7. Any tips on adapting it?

Thanks in advance for any advice - Bob WA3R

Is not a dumb question , yes you can use the metal film resistors in place of carbon type , be aware that they are not as tolerent of overload as carbon ones . they are used as fuses in some television circuits . not sure I would use them in any tuned circuits as they are probably slightly inductive . if you can find them the carbon film type may be a better choice .

Bob,

Are you sure that the mic element is connected when the mic isn't keyed? If VOX only works when you key the mic, it looks like VOX circuit works but no signal is getting to it until you key it.

Best choice for Cathode resistors is ceramic composition, Ohmite OX and OY series. The film resistors are a problem not because of 'inductance', which is negligible at these frequencies, but
for peak current carrying capability. These resistors can see very high currents during tune-up
when off-resonance.

The popping AVC may be a result of the receiver's RCVR SENS setting, per Section 6.4.9 of the
manual. Some reduce this level because it makes the receiver 'sound hotter', but needs to be set to
-1.35 VDC with a HIGH impedance meter, VTVM or quality DMM with input impedance of 10M or more.

I've checked a number of small metal film resistors on
a Boonton RX-Meter up to 250 mhz. For values as high as 40k
the reactance was insignificant at least to 100 mhz. Smaller
values will have even less. I've replaced componsition
resistors in the ring modulator circuit of a 4B with no
problems other than the original resistors were actully OK
(trying to find an elusive problem). I think there are few
applications where metal film resistors can not be used in
place of carbon composition resistors. Carbon comps may take
higher momentary overloads but that's not enountered in most
circuits.
BTW, not all carbon composition resistors change a lot.
In theory they all go up in value over time but I've found
that the amount varies a lot with brand. Ohmite and
Allen-Bradley resistors, both of which have shiny seamless
bodies, seem to be much more stable than the ones in cases
with seams along the sides. I don't know who made those but
all are worth being suspiciousl of. Resistors run near the
limit of their dissipation are likely to be out of spec.

Personally, I'm leary of ANY old carbon comp. resistors-seam, or no seam..unless they are REALLY difficult to swap, it may be worth considering doing a pre-emptive strike, and just swap them ALL.
(yes it's a lot of work, but the improved reliability is probably worth it)-anyway odds are at least some of them are way off value(they generally go high).

This is really not practical in the B line because many
of the components have virtually no leads. In addition, a
lot of circuitry is very sensitive to stray capacitance so
the position of each component is important. I've measured
enough old resistors to have considerably more confidence in
their stability and the brand _does_ make a big difference.
There are some under rated resistors in both TX and RX but
especially the transmitter and they are very likely to be
considerably off value, I think Garey Barrell can list the
most likely, but others should be left alone unless you have
a definite reason to suspect them. Also, most of the
non-electrolitic caps in both TX and RX are of very high
quality and are plastic, not paper. I've yet to find a bad
one. The electrolytics are a differnt story and are
frequently bad. Can electrolytics that are exact
replacements for the originals can be had from Hayseed
Hamfest, these are completely new caps, not re-stuffed old
ones. The AC-4 power supply should be rebuilt using the kit
from The Heathkit Shop, which replaces all the caps, power
resistors, rectifiers, and puts all on a modern circuit
board that will make future replacment much easier. Its a
few hours work to assemble and install it and its not
expensive.
I am a great believer in the rule that "if it aint broke
don't fix it."

Richard -

The inductance of metal and carbon film resistors is negligible for our purposes, i.e., below 30 Mhz
or so, and even up into the VHF range. There ARE however instances where than 'insignificant'
inductance 'may' be a problem at VHF and up. I have seen problems occur, particularly in VHF
amplifiers, of parasitic oscillations that were 'cured' by replacement with carbon (or

ceramic)
composition resistors.

That aside, carbon or metal film resistors are not a good choice for the Cathode resistors in the
Drake transmitters. Film resistors are fine, quiet, stable resistors, but are quite weak in current
handling capability. That film is THIN!! As you know, higher currents can occur during tune-up or
other off-resonance conditions. I suppose you could consider film resistors as a poor fuse, but I'd
prefer that they just stay as resistors of the correct value! :-) I don't use anything but Ohmite
OX or OY ceramic composition resistors in this application.

By the way, I think Stackpole was the manufacturer of the 'pebbly' bodied resistors.

To expand a little on the other Bob's answer .... The +3 preferably should be connected to the high-level input pin on the mic connector, assuming your rig has the added 470K inside the radio. It will work fine on the low level pin, but yout gain adjustment might be a bit more critical and the rig will overdrive more easily. FWIW, my +3B scored high marks on my TR-7, beating out most other mics I tried as the favorite amongst my friends. I've never run VOX with mine, but the RELAY/ELECTRONIC switch in the bottom of the mic can be rigged to open the PTT line so you can run VOX with the radio.

> Question 2 is: I have a number of mics available (D104 G-stand, Electro voice 719 high impedance ceramic, and a HEIL HM-10). I really wanted to use the HEIL, but I'm sure the impedance is too low for the TR7. Any tips on adapting it?

Any of the above should sound very good. The D-104 and the EV should be run on the high level input, and and with an additional 470K in series with the audio line (~1 Meg total load impedance), the D-104 will sound very good. I've also used an EV-729, Turner 254HC, and various other mics. The TR-7 isn't too fussy about what you use with it, the ultimate choice will be based on the characteristics of your voice and your operating style. I use a Telex Echelon ANC aviation headset for contesting.... :)

that's why I said unless they are difficult to change.
Also, yes brands can matter-some companies use better quality parts than
others.
As far as swapping caps....electrolytics are suspect, paper dielectric caps
are generally lousy, but most other caps will generally be ok.....although
some mica caps can get silver migration issues.
When I'm talking about changing carbon comps, I'm talking in a general
sense....the ones used in typical consumer electronic stuff are generally
worse than commercial stuff, for example.
Another example:Zenith transistor portable radios have less electrolytic cap
failures than some other brands(however, watch out for the ones that have
SOLAR brand caps-they were less reliable).

There is a problem with very high value resistors of
enough voltage between the "windings" to cause an internal
arc and open the resisistor, very rare. Overloads vary, at
the resistor factory I wasted part of my youth working for
in the dim, distant, past we found that carbon film
resistors would run at red heat before they would fail.
Composition resistors do seem to be more resistant to very
short pulse type overloads.
The pebbly surface resistors were IRC. That surface was
supposed to dissipate heat better because it had a slightly
larger surface area. I think Stackpole made precision carbon

resistors but am not sure. I don't know who made the seamed resistors but I am also not sure that the couple in my Drake stuff were original, all the others appear to be Ohmite. Drake seems to have used the best quality components, any economising was done in some other way. The more I learn about Drake and about other equipment of the time (like Collins) the more impressed I am with Drake's engineering. The stuff was about half the price of Collins equivalents and for the most part works better.

I don't work with tube output stuff, but I agree that ceramic composite resistors are a better choice, although if you choose properly, a film resistor may be ok too.

> Any of the above should sound very good. The D-104 and the EV should be run on...

Adding to Jim's comments, impedance matching for interstate audio components hasn't been used for the past half-century. If there's no reactive component (e.g., transformer), the general rule is to drive with low-Z at the source and terminate into moderate to high-Z at the destination. The upper Z limit at the destination is only limited by noise and RF susceptibility -- and those issues are managed with high common-mode rejection inputs and often without the need for ferrite.

The only other time impedance matching becomes a concern in audio circuit interfacing is when an unusually long line is driven (e.g., a mile-long copper telco circuit -- the one's that still exist!). Long twisted pair audio lines begin behaving like transmission lines and optimum performance generally occurs when the source and destination Z are equal in relatively low-Z ends.

So, go ahead. You can safely drive your transceivers from a 1-ohm audio source, even if the mic input is a High-Z load.

You can do a lot of work with little return by changing resistors that are good. Check before you change. Not all are out of the 10% Specification.

And while we are on the subject, be sure your test equipment is appropriate for the job you are doing, and your test leads are good.

The main concern is voltage output of the microphone and
voltage gain of the input stage. Crystal and ceramic
microphones have quite high voltage output but have internal
impedances that look like capacitors, they must be operated
into as nearly an infinite impedance as possible if there is
not to be frequency discrimination. Moving coil and ribbon
microphones are inherently very low impedance and usually
require a step up transformer when used to drive a vacuum

tube or certain kinds of solid state amplifiers. Typical moving coil microphones have a voice coil impedance of around 50 ohms and for medium or high impedance will have a built-in transformer. They are sometimes used for low impedance inputs without a transformer at the microphone. Ribbon microphones have _very_ low inherent impedance, an ohm to ten ohms and _always_ have an internal step up transformer. _ALL_ of these microphones work best into an infinite impedance but will work well if the amplifier input impedances is several times the maximum impedance of the microphone. For medium impedance microphones i.e. 200 ohms, an input impedance of around 5K is enough. Generator type microphones should _never_ be operated into a matching load since that will reduce the voltage by half plus may cause frequency response deviations. Microphones are voltage sources, not power sources. Microphones with built in amplifiers or active impedance matching circuits, like condenser and electret types, can have any output impedance desired and can drive any load impedance desired.
I low or medium impedance microphone will work fine when connected to a high impecdance amplifier but its voltage output may not be sufficient without a step up transformer. Such transformers are still made and are available although perhaps not cheap.
Now to cut to the chase, try the microphone. If it has enough output to drive the transmitter sufficiently and sounds OK it doesn't need anything eles. If it doesn't have enough poop to drive the TX try a matching transformer.

Thanks guys for the info. After much experimenting I think the Turner +3 is the way to go. It seems to have the smoothest audio of the aforementioned mics. I have the gain control on the mic @ 10'oclock and the mic gain on the TR7 @ 11'oclock. I'm guessing the the audio "smoothness" can be attributed in part to the +3's compression. I haven't wired up the HEIL yet, but I plan to try that as soon as I get some free time. Thanks again! - Bob WA3R

Sounds pretty close to where I have mine set up. Of course, the gain setting varies from band to band, and I run mine through an SP-75 speech processor as well. The +3 seems to do very well, and I have used it for casual contesting and DXing. I'm generally against preamplified microphones, but I make an exception for the +3 since it gets such good reports. I have another one that I may just try disconnecting the amplifier in some day - which would essentially turn it into a Drake 7075.

Try it out with some people that are local to you and who know your voice, and will give you honest assessments. What I got was that the 444 varaints have an excellent natural sound that is quite sutable for casual ragchewing, while the +3 and other ceramic/crystal mics are better for DXing and contesting - although all of them sounded quite good.

Over the years I acquired some type of 444 variant (I think). Any ID decals that might have been on it are long gone. There's an unmarked switch on the bottom that must be electronic/relay switch. Anyway, I tried it on the TR7 and, although it was much louder than the Electrovoice 719, the shure seemed very "muddy" (heavy on the lows). I'll have to tear it apart and see if I can figure out what exactly it is. I imagine there's some ID on the element. Of course, the distance from lips to mic plays a pretty big role in the overall sound as well. I'm generally about 4" to 6" from the mic which allows the room to add to the sound.

I'm also having a problem with my transmit audio feeding back through the speaker. It doesn't matter which mic I use. Any ideas?

Something funny here... The published curve for the
Shure 444 shows it to have a very steep rising
characteristic, about 10db peak at about 4khz up from 1khz,
quite high Q and probably gives it a bit of the sound of a
very old fashioned telephone. The low end rolls off very
steeply below about 150hz. If its muddy it might be from the
electronics inside (the version I looked a was not
amplified) or possibly because it is overloading the AGC in
the TR-7. Working distance should make no difference in a
pressure microphone although working it close will further
increase the output level. I can't find a data sheet for the
old Turner mics. The D-104 has a similar but less
exaggerated peak.
Many microphones designed for CB use have built-in
compressors and sometimes rather radical equalization both
of which can destroy naturalness and, if there is enough,
also destroy intelligibility.
In modern sideband rigs we are dealing with a _very_
limited audio frequency range, maybe 2khz, older rigs with
mechanical filters might pass 3khz. Most of the time there
will be another similar filter on the receiving end so what
is being called bass and treble are very relative.
Also note that limited frequency response is helpful
only in noisy systems with limited power capability, where
the noise level is low both frequency and amplitude range
reduction _reduce_ intelligibility. Since transmission over

a noisy channel is common for ham radio the use of filters
to reduce the bandwidth to the frequencies most important to
conveying intelligence in speech is justified and a certain
amount of compression or peak clipping will help in
overcoming noise at the receiver. However, there is
definitely a point of diminishing returns for both.
Every so often I hear someone fooling around with
equalizer settings. Invariably they sound better when the
turn the damn thing off. I also hear signals that are
excessively compressed making them muddy. The test is how
well the speech can be understood in the presence of noise,
not how high it jacks the meters.

Have you gone over the alignment procedures? I don't
know the TR-7 well but in my TR-4 there is an adustment
called driver neutralization for just this effect, perhaps
the TR-7 has a similar adjustment.

Thanks Richard,

I have no idea what element is in the Shure mic so it's a wild card at this point. I'm not even sure at this point where it came from! It's been on the shelf for years and never saw any use.

As for the alignment, I plan on doing that today or tomorrow. - Bob

Hi Bob,
Shure made a variety of Mikes that used essentually the same plastic body as the 444,
I have one here, which is a 600 ohm unit, probably for P.A. use.
Shure on their website, allows you to search for info on all their old mikes, but I have never
been able to identify the Mike insert number, from the number on the label of the insert itself.
If you work it out, please let me know.
On my real 444 I have a small 3 resistor pad, as I found originally the 444 overdrove the TR7.

Good Luck

http://www.alg.myzen.co.uk/radio/tr7/mods.htm

Mod #1.

Also, *highly* recommended is #18. Other mods there are worthwhile too, depending on what you want. #7 will not work if your rig has the "standard" Drake-provided general coverage transmit mod, you need my "better allband transmit mod" or GW4ALG's #15 (which mine is based upon, but enables the two missing ranges).

You will want to run the gain so the ALC LED *just* flickers occasionally on voice peaks. That is your overdrive indicator.

The switch on the bottom could be PTT/VOX swiitch or a high/low impedance switch, depending on the variant. I don't know how many transistorized 444 variants were sold into the consumer market, but I have never seen any. The only ones I have seen are commercial variants designed for specific commercial radios that require a preamped mic. I have the classic 444 (high impedance) and 444D (dual impedance), as well as a Johnson commercial variant with the split PTT bar facilitating a "monitor" switch. They always garnered good reports, never "muddy", but have been characterized as more "mellow" and "natural sounding" than the D-104 and other ceramic/crystal mics. Of couses, as you mention, the "proximity effect" will alter the low-end response of almost any dynamic mic (expect for the EV RE-20 broadcast mic). In all cases I've run the 444s in high impedance mode (where selectable) and on thi high level input pin when used on the TR-7.

I don't think this is a directional microphone. The
explanation given here is _almost_ right, perhaps it is
completely right but I did not read it carefully.
Proximity effect is caused by the curvature of the
wavefront close to a source. The effect has an analogous one
in RF were the pattern of an antenna is different in the
"near field" and for the same reason. Pressure microphones
are not responsive to proximity effect because they measure
the instantaneous pressure in a wave front against a fixed
reference, that is, the pressure in the case. While
practical pressure microphones have an air leak to equalize
the pressure over long periods, mainly the variation from
atmospheric pressure, the pressure inside the case, effectly
on one side of the diaphragm, is fixed. They are technically
known as zero order gradient microphones. In a directional
microphone of figure eight or cardioide pattern the driving
force on the diaphragm is due to the difference in pressure
in two different parts of the same wave. The diaphragm is
arranged to sample the pressure at two points closely
separated. When a single set of sampling ports is used the
system is called a first order differential or gradient
microphone (both terms are found in the literature). Now, as
it turns out the difference in pressure at two points in a
wave depend on whether the wave is curved or plane. At
considerable distance from a source the wave can be
condidered to be a plane wave but, when closer than perhaps
a wavelength, the wave is curved enough so that the inverse
square law begins to produce a differece in the pressure in
the two parts of the wave. As a result the closer one is the

greater the difference so there is a rise in the driving force which is proportional to frequency, or, rather wavelength.
This difference does not affect pressure microphones but causes a rise in the low frequencies of conventional directional microphones. This effect is put to practical use in noise-cancelling microphones which are differential types intended to be used very close to the source. While differential microphones made for general use are designed to have flat responce at a distance the noise cancelling microphone is designed to be flat at some very close distance, perhaps half an inch. This results in a very great reduction of low and mid-frequency responce for distant sounds.
Alpha M Wiggins, a designer working for Electro-Voice came up with a scheme to make the frequency responce of directional microphones essentially independent of distance and also make the driving force constant wiht frequency. E-V called this Variable D. The D is the distance or path length from front to back of the diaphragm. In conventional directional microphones this is constant. In the Variable D microphone a filter is used behind the diaphragm to separate entrance ports at various distances. In the first mic, the model 666, this was in the form of three lumped constant filters. Each filter has an entrance port at a distance from the front of the diaphragm and is connected to the back of the diaphragm. In the 666 the range of frequencies was devided into three parts with three ports. In later microphones like the RE-15 and RE-20, the filter is a continuous transmission line with essentially an infinitely divided series of ports of continuously varying distance. Since the effective distance increases with wavelength so as to produce a constant driving force, the larger percentage of distance in the waveform is less sensitive to the variation due to distance and the proximity effect is substantially reduced (but its still there just a little).
There is another benifit of this system: since the driving force in a differential microphone varies with the frequency something must be done to equalize the frequency responce. In the case of conventional microphones using "dyanimic" elements (moving coil or ribbon) the output is proportional to the velocity of movement of the conductor in the magnetic field. In these microphones the output can be equalized by placing the primary resonance below the band of frequencies of interest. That way the motion of the diaphragm will be constant velocity when driven by the decreasing force of the wave. This works but can make the microphone quite sensitive to mechanical vibration and wind noise. Since the EV system produces a constant force the diaphragm can be resistance controlled as it is in a

non-directional microphone and still have flat frequency responce. It has the virtue of having substantially less sensitivity to mechanical vibration and wind noise. There is more to the story but I think I've gone far enough already. The point is that if the microphones under discussion are non-directional they do not have proximity effect, if they are they do. I now don't remember which mic I found the data sheet for, probably Shure because they have data sheets for practially everything they ever made on line but I think this was a pressure mic (maybe not) and I have no idea of what the other was.
BTW, Electro-Voice blew everyone else out of the water when they began making the 655 and 666 microphones. They had flat responce, high output, light weight, were relatively low cost, and were indestructable. Many broadcast stations, both TV and radio got rid of everything else. Recording studios were more likely to use the newer condenser microphones becoming available then but even there the EV mics were good sounding enough to be frequently used. They killed RCA and Altec.

Preaching to the chior, Richard. :) I work in the factory service center, a few feet away from the guy who still actually fixes RE-20s. (Most of the other mics are offshore manufacture now, and it's far cheaper just to throw them away and send the customer a new one). Only the high end broadcast mics (RE-20, RE-27, some of the condensers, etc.) are still manufactured at the facility I am in. I see the bones of the gutted RE-20 elements that he replaces almost every day, quite an interesting design.

As for the rest, I don't quite buy that the 444 series is completely omnidirectional in nature, but I;ve never actually experimented with possible proximity effect. Generally, I prefer to close-talk a microphone for signal-to-noise ratio reasons (think about the CBer in his armchair with the "lollipop" on the table cranked up, and you can hear the wife, the kids in the next room, the TV across the street, and the pit bulls fighting down on the corner).

I used to sell the stuff, met Lou Burroughs a few times
but never saw him pound nails with a microphone:-)
The Shure 444 is a controlled reluctance
non-directional mic. All non-directional microphones are
actually directional above some frequency. The frequency and
degree of directionality is due to diffraction which it turn
depend on the size and shape of the case, the large it is
the lower the frequency at which the mic begins to be
somewhat directional. Given a fairly symmetrical shape the
pattern will approach a "super-cardioid" at some frequency.
Above that it will begin to develop lobes but for ordinary
size microphones that doesn't happen in the band they are

sensitive to. For a fairly large mic, say an Electro-Voice 6d5 (the old chrome one) the mic will begin to get directional around 1khz and at around 4khz will be almost uni-directional. The 635 data sheet illustrates this well. In addition to becoming directional the diffraction causes an effective increase in pressure at the diaphragm causing a rise in the frequency response up to the point where the effective diffraction diameter becomes a wavelength, at which there will be cancellation (the path length is half a wavelength). As the frequency continues to increase the response will have a sineX/X characteristic. Again, the high frequency limit of most microphones is too low to permit this. It can be demonstrated using a laboratory condenser mic with a large flat, round, baffle attached to it.
Electro-Voice began making truly high fidelity moving coil microphones around 1948 with the models 648 and 650. These were odd shaped mics (the 650 truly looks like a hammer) with high output (-48 for the 650) and response of +,- 2.5 db from 40 to beyond 15khz. They were quite flat and very smooth but had the usual directional properties at high frequencies. They were among the first microphones to employ the new Electro-Voice diaphragm material called by them Acoustaloy. I think this was mostly Mylar but am not sure. Other microphones used spun aluminum or cloth re-enforced Bakelite. The former was delicate and hard to make, the latter rugged by was too massive to have good high frequency response. The new Electro-Voice material allowed both ruggedness and very good frequency response. It as also easy to make in production so reject diaphragms were rare, additionally all the mics sounded exactly the same.
In 1953 Howard Souther of EV designed a new microphone designed for TV. This was the 665 a tubular shaped mic with outstanding frequency response. By using a diffuser in front of the diaphragm Souther both extended the high end and caused the pattern to widen out so that the microphone was much closer to being truly non-directional than most others. This mic had an accessory wind and blast screen which soon became integrated. The next mic was the 655C which was similar but had the response extended to beyond 20khz, an unheard of response for a moving coil mic. I mentioned before the model 666 designed by Alpha M. Wiggins, also the designer of the famous Circlotron amplifier. I could write more about the impact that these mics had on the industry. In fact, the other US manufacturers had pretty much sat on their hands with the exception of Altec-Lansing with the M-11 condenser microphone system. It was excellent but double the price of the 655. RCA also came out with a hand holdable mic for TV use called the BK-4, this was a pressure ribbon mic with quite good response but it weighed nearly two pounds and cost about $450, it was also somewhat

delicate. I never saw one used outside of NBC.
Conrolled reluctance microphones are a version of the
old magnetic mic. Cheaper to make than a moving coil mic and
far more rugged than a crystal mic. Shure used the same
system in its famous stereo phonograph pickups. It can work
by either moving a vane in a magnetic field usually with the
pick up coil wound around the magnet, or by moving a small
magnet in a pole structure again with the coil wound around
it.
I promise I won't get this OT again (at least not so
verbosely OT).

Richard, you've really got me curious now. I've read many of your posts, on a great many subjects. How is it that you came to know so much? Not being sarcastic, I've come to look forward to your comments on any given subject. :)

Mostly just curiosity. I read a lot. I started out to
be a physicist but found my math was not up to it.
Nonetheless, I am fascinated by mathematics and try to
understand it up to my limit. I've always been interested in
the sciences, I don't remember ever not being so. Its
sometimes frustrating. Other interests beside electronics,
which has been my vocation, were photography, theater, and
sound recording. I guess the latter goes with electronics.
Also music. I don't play an instrument, another frustration.
I had piano lessons when I was perhaps seven but they
stopped just about when I got serious about it. I learned to
play with both hands and read music. All gone now although I
suspect I could get it back.
I work in television in an engineering capacity for Fox
Television. Our network headquarters are here. While the
network does not operate a great many hours we also
originate at least a dozen cable channels and insert
commercials in others. Broadcasting used to have some
glamour in it, all gone now and I can't wait until I am in
financial condition to retire. Been eligible for several
years and at seventy I am bored stiff with it.
The Elector-Voice variable-D system is a special thing

for me because my serious study of acoustics began when I realized I didn't understand it. Olson's book was of limited help. I think I pieced together the answer from several sources.
I also don't remember where I first saw an explanation of what "near field" really was, it may have been in some treatise on antennas. The idea that the curved wave front and the inverse square law was the cause was a sort of epiphany, it all became clear. Now, I am not so sure that the same is true for electro-magnetic waves in the vicinity of an antenna. Acoustic waves are true compressional i.e. longitudinal waves but electro-magnetic waves and light waves are considered to be transverse. The relationship of the electric field to the magnetic field becomes very complex in a wave with a curved wave-front. This is why antenna patterns and intensities must be measured at several wavelengths for the measurements to be meaningful for the distant field. The detailed math is beyond me. If you are interested in this stuff John D. Kraus's old book on Antennas is a good one. He at least makes an attempt to explain things on an elementary basis before becoming precise. BTW he is the inventor of the once famous 8JK antenna. I just discovered that there is a recent revised edition of this but its about $150, too rich for my blood, I'll stick with the old one which I bought new a million years ago.
BTW, I worked for Hewlett-Packard for about ten years beginning in the mid-1960. I probably would still be there but my mom got very sick and later I decided to do other things. I was mostly working on microwave instrumentation. I thought I remembered a lot but don't really.
Oh, well I am just rambling now. Time to get some sleep.

Thanks for the Ramble, Richard. Very interesting. You're a bit more
well-travelled than I am, it would seem. Between you and Garey, I should just
keep quiet... :)

Seriously, a fellow I work with compared me to Cliff Clavin once. I wonder what
he would think if I told him that there is someone out there who makes me look
like a piker most of the time.

I am not sure I am so well travelled. When I was a kid
my family travelled around quite a bit so I've been in many
states for a short time. Lived in Miami Beach for most of a
year, the summer weather was enough to discourage my family
from settling there. I've been to England a couple of times
and had one of those two week tours of Europe. Never do that
again, you see a lot of stuff briefly but also miss some
really important things. Its also very tough if you get sick
travelling especially in a foreign country.

5589. Source for Xtals for R4B?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-07-15 11:35:40 UTC
From: Ralph
Topic: 5589 Message: 5589

Just had the good fortune to reacquire a Drake R4B -- beloved receiver used in the 1970s for shortwave tropical band DXing. Will be refurbishing this gem, a labor of love.

Couple of questions for the board:

1. Anyone know a source for the outboard xtals you plug into the back of the rig, to add fqy ranges. I need an xtal for the 60 meter band, 4.5-5.0 mHz, meaning it would be an xtal for 15.6 mHz (the formula is to take the lowest fqy of the desired band and add 11.1 mHz to get the xtal's actual fqy).

May need other ranges, too, not sure yet.

I've seen these randomly show up on eBay from time to time, but does anybody know a direct source I can avail of?

2. I used to also have a crystal slot 'extender' -- a box with 3 or 4 xtal sockets which I could plug into one of the xtal sockets in the back of the R4B. This would allow me to increase the number of additional xtals being used. Need this to have complete coverage of the bands I want . . . anyone have any thoughts re where I can pick up one of these?

Cheers,

Ralph

Ralph,

You will find either of these people can satisfy your crystal requirements. Both have their roots in ham radio.

http://www.icmfg.com/

http://www.jancrystals.com/

Both have been around for many years and provide a quality product. I have purchased from both and have been very satisfied with the products. Both will have the technical specifications for the crystals you need so you should be able to tell them what you want and they will calculate the frequency.

Have fun with that little receiver. It is a great piece of equipment.

Thanks for that assistance, Jim!

Now, if anybody knows the whereabouts of one of those xtal socket number extenders, I'll be totally all set! I suppose I could also build one, but would rather buy something professionally done. All it does is turn one socket into multiple sockets (think I had a 4-for-1 extender before).

Ralph,
It is okay to SWL around the 5 meg frequencies (old tropical band), BUT the 4 Line Drake isn't a good candidate for 60m usage (ie, transmitting at those frequencies). Search the archives where you will find more info and Garey will clarify more when he gets online later.
73, and enjoy those Drakes!

Ralph -

The R-4B isn't a particularly good choice in the 4.5 to 5.5 MHz range. It will work, but due to the
2nd Mixer LO being at 5.595 MHz, the PTO tuning from 4.995 to 5.455, and the IFs at 455 and 50
kHz. As you can see, there are a LOT of potential spurious responses. Transmitting is a definite
no-no, but the receiver is ok as long as you realize there are going to be 'extra' signals in that
range.

International Crystal Mfr <www.icmfg.com> is an excellent source of reliable crystals. Ham owned,
with data on file for anything Drake ever made. Just tell them what frequency you want to cover and
what unit it's for and it shows up! Most important, they are ON FREQUENCY, minimizing Band-to-Band
calibration adjustments.

I don't know of the crystal 'multiplier' you're referring to. The old Johnson Viking II transmitter
had a ten position socket and associated switch.. :-)

Thanks for filling the gaps for me, Garey. I can't do all that off the top of my head anymore. I've been outside trying to solve issues on the 80m wire, but it's 114 in the shade, and there's just not enough shade for this old guy and I've given it up until in the morning EARLY, hi. It's about 73 in the house (no coincidence), so I guess I'm in for the duration.

And before Garey's hint goes any further, Ralph, you may NOT have the crystal switch out of my nice Johnson Viking II as I plan to use it!!!! Someone may have a junker 4 Line transmitter or receiver chassis with one of the crystal decks still whole. That could be outboarded easily, but I would think short leads would be key.
73 all,

Does anyone have a junk t4 or r4 chassis that has the RF Tune or Preselector control in it? I'm looking for one of these drives for my R4 B receiver. I need the red pointer and knob also. Thanks,

Lawrence, WA4BHK

Well then, perhaps the fish are the key?? :-)

I've never tried the receiver, but the transmitter looks like a Christmas tree in that range. Seems
the receiver would have similar problems.? Do you find ANY signals in that range with no antenna??
Just a few? Lots!?!

5603. Re: Source for Xtals for R4B?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-07-16 11:58:07 UTC
From: Ralph
Topic: 5589 Message: 5603

Wanted to thank everybody for pitching in on that info I was seeking re the R4B, xtals to extend to additional 500 kHz ranges, etc.

I used the R4B extensively in my younger days, in the 1970s, to DX Latin America, Indonesia, Africa from my Midwestern USA QTH . . . and yes, the caveats were already communicated about possible 'bugs' in the 4.5-5.5 range. But with that in mind, it was easy to tell when something was a rx artifact versus a real xmsn.

The R4B was a real whiz on the tropical bands, actually ESPECIALLY on the 60 meter tropical band, what with the rx's terrific capability for exalted carrier SSB reception, its highly effective IF notch, very good receiving sensitivity, nice range of bandwidth selectivity choices . . .

Again thanks to all on the xtal sources. Now, if I could just find an outboard plug-in xtal socket box, to add more seats at the xtal party, I'll be all set! ;-)

I've got an original cut sheet dated Dec. 1979 on the 254HC & 454HC, but doesn't have wiring info. The difference between the two seems to be freq response, 100-8K for the 254HC vs. 300-3K for the 454HC. The generic Turner wiring booklet should cover wiring. I can scan this and send it along if you want.

A good source of Turner info on the web:

http://www.ericbraun.com/turner/

Or Google for "turner microphones" if you have some time to kill.

Dick at one time Turner had spec listings on the net. But recently I went looking and couldn't find it. I also have a 454X with no instruction sheet. As a matter of fact I couldn't find it on the Turner page. I don't think it is a rare mic, yet very little is available info wise. If you find anything please share as I like to have data sheets on things I own (or used to own).

The Turner Wiring Booklet will tell you most everything you need to know about how to wire them:

http://www.cbtricks.com/members/toban/turner/turner1.htm

http://www.ericbraun.com/turner/Turner%20Mic%20Wiring.pdf

As for specs, they seem to be similar to the 250 series in style, but with a frequency response tailored for communications. The "X" apparently means crystal element.

There were two models of 454, X and C. Both tailored for ssb response.
X=crystal
C=ceramic
Ceramic elements are preferred as more rugged, less succeptable to humidity
I still use my 454C almost every day on the S-line and Drake line and it
gets great reports even after all these years and being dropped a few times.
Sorry, no data sheet. Got it used at a hamfest decades ago.

>One of the things I did today was run an A/B between the +3 and a super sidekick. The +3 was the hands down winner with a much flatter response. The SSK was more low end oriented - kinda "muddy"

That's usually the difference between a dynamic and a crystal/ceramic cartridge. I have used the highly regarded Shure 444 also, and while they sound quite good and very "natural", they lack "punch" in the mid/highs that tends to work better for DXing and contesting. As I mentioned, individual voice characteristics and operating style are the main factors in type of microphone - more so than the name on the outside or the catalog price. :) I've gathered a flock of EV broadcast and stage mics to play with sometime, including the "legendary" RE-20, and various other dynamic and condenser models. It will be interesting to play with them and see how each sounds though a narrowband communications channel.

It will 'work' if you install a 12.1 MHz crystal, but not very well. Properly aligned, the 4
Series _Preselector_ will just barely go down to 1.8 MHz, the bottom of the 160M band. The sensitivity drops off drastically below that. I have been able to receive stations around 1500 with
the 12.6 MHz crystal, but with greatly reduced sensitivity,

The 'correct' way to get MW on the 4 Series is with an 'up-converter", which is essentially a mixer
that translates the 0.5 - 1.5 MHz range up to, 28.5 - 29.5 MHz via a 27.5 MHz crystal LO. Drake
marketed such a device, the 4-LF, but they are quite rare.

Doc,
I'm no help on the sidetone, but several vendors now sell replacement Drake knobs with set screws that will solve that problem. I've always broken them when trying to "bend" them for a little more tension. I'd just bite the bullet and buy a few. Look on WB4HFN's site, and I think you will turn up some vendors, or Google "Drake knobs" and I know you will find them, hi.

Doc -

Ty Al, KC9YS for replacement knobs with set-screws. Tell him I sent you and he'll give you a good
deal!!

On the warble... When does it vary? When you tune does it jump in little bits? Does it just wander around while sitting still? How much does it change? Does it do it on all bands? Does it
do it on the Calibrator?

Hi Garey,

Thanks for the response..

When you tune does it jump in little bits? No, it behaves itself when tuning...

Does it just wander around while sitting still? Yes

How much does it change? about 300 hz

Does it do it on all bands? Yes

Does it do it on the Calibrator? Yes , it does
Cheers

From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5624

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

Doc -

I'm not sure if you have NO calibrator signal on 15M or if it's just too far off frequency.

If no signal at all, it could be dirty switch contacts, crystal contacts, or a dead crystal.
Plugging and unplugging the 15M crystal a few times might help. There is a procedure in the manual,
5-10, for adjusting L5 for 15M. If no luck, then it's almost certainly a dead crystal.

International Crystal MFG <icmfg.com> can provide a replacement.

It would be useful to have another signal source of
known frequency. That would tell you immediately if the dial
calibration is way off. I am not sure about the TR-4C but on
many other receivers the calibrator is connected right at
the antenna input so that its ouput can be heard on another
receiver by connecting both antenna terminals together (be
carefull not to transmit into another receiver), Actually a
couple of wires should be enough. That will tell you if the
calibrator is putting out on 15 meters. These two tests can
help to isolate the problem.

I can hear the calibrator on 15m its just to far waya. on
all other bands its dead nuts on.
Cheers
Doc
W2MFT

I have to agree with Garey that its probably the 15
meter crystal. Try cleaning its pins with a pencil eraser
and put a little Deoxit on them. The wiggle them in the
socket a bit to clean the socket. My guess is that it won't
fix the problem but is worth trying. Crystals do age and
some of the older ones can drift pretty far. The handbook
should state the actual crystal frequency and it should be
printed on the case. One way to check it is to use another
receiver to hear the oscillator. I think the fix is to
replace the crystal. I have had good luck with International
Crystal. BTW, I found a crystal in a Collins R-388/51J-3
that was about 5 kc off. I got a replacement from IC that
was exactly on frequency.
If you have done all the voodoo with cleaning the
bandswitch (must be done thoroughly) and other stuff there
is not much left.

Thanks Richard.

I pulled the crystals and made sure they were clean and re cleaned all the tube pins as well. It most likely is crystal...I found the 2nd 10 meter rock to be the same as the 15 m rock as well.

The rig is a really good looker and it was very clean when I got it...It came from an old friend who passed...It just has a few problems that I am working through.

The biggest one now is that sometimes I hear the t/r relay go from transmit to receive but its like the vox circuit isn't releasing...it stops transmitting but no rx ahd then I tap the key a time or two and it comes back...

So I am having fun learning all about this radio and really enjoying it.

Garey has been a big help....I'm going to get the disk I figure that would be a big help. I want to thank those here that help and I don't want to be thought of a user...its just I don't really know where to start...but thanks to you guys its starting to behave a little better...I operate almost all cw and I have a datong for it and it amazes me how well it hears.

Well if anyone has any thoughts about the t/r I would appreciate hearing them...I don't know if there is something I am missing with the vox anti vox adjustment or what??
Cheers

Doc -

Your T/R problem sounds like a relay problem. There is one set of contacts that control T/R. The
'arm' is grounded, and the contacts are connected to the XMTR K and RCVR K. When the relay is
closed, the XMTR K contact is grounded, and when the relay is open, the RCVR K is grounded.

First check. When it 'seems to' stop transmitting and failing to receiver, what happens if you turn
on the CALibrator? Tune to the nearest harmonic and see if the CALibrator can be heard. If it CAN
be heard with the receiver still 'dead', then the problem may be the antenna switching contacts. If
you cannot hear the CALibrator, the the RCVR K contact is not being grounded.

If you unplug the relay, the plastic cover can be removed by carefully prying it away from the base
at the center of each long side. There is a small nub. Pry the cover up until it can be lifted
off. Then take a piece of paper and spray or drop DeoxIT on it. Then place it between each set of
contact faces and withdraw with the contacts 'closed'. This should clean them and get you working
again.

Doc, Do be careful of that relay. Over the years I have always been able to find replacement relays for anything I needed but had a shock this past week. I have an Ameritron AL-1200 that developed a problem with the antenna relay, the contacts for receive pass through were dirty and when I went to receive the receiver couldn't hear much of anything.

I tried cleaning the contacts and weren't very successful, beside that when a relay starts to give trouble it will quit eventually anyway. So I called Ameritron and to my amazement they told me that relay wasn't available. The amp was built prior to 1999 and used a 3PDT, stud mount, open frame relay like I had seen millions of times. The tech told me to "google" for the manufacturer part number and gave me that number because the current production amplifier uses something completely different which would not be easy to modify.

The search retuned three hits in the US. The one I settled on was RJ Components which is a wholesale group. Mouser shows the relay in their info but would have to buy something like 30 of them from someone like RJ to sell to me, not the normal 1. So I called RJ and they have a retail web site and they transferred one of their stock over to that website to sell by CC.

The real shock is the relay was $35 and shipping and handling made the final price just over $48. So do be careful of your relays guys. The guy at RJ told me that they are the largest purchaser of legacy parts in the world. For example, they purchased the final stock of Allen Bradly carbon composition resistors when AB quit making them. They have a lot of stuff but even they didn't have one of the other relays in my amp. These mechanical relays are becoming very expensive and hard to find. So treat it with care and don't bend the arms, then pray it holds from now on.

Jim/W5JO

If you unplug the relay, the plastic cover can be removed by carefully prying it away from the base

Good advice. I don't think it applies in this case, as the unit has been stored for a while and
probably just has a film of corrosion on the contacts. These contacts are 'self-cleaning', i.e.,
when they close they actually 'scrub' against each other. But a little DeoxIT does it faster and
easier than multiple actuations.

Mouser and Digi-Key have about 200 of the P&B R10-E1Y4-V2.5K, but the price HAS gone up! Last year
they were about $16, now they're $25. So buying a spare might not be a bad idea. The same relay is
used in all the 4 Series transmitters, stock in later models and replacements for the wired in
earlier versions with a small mod PC board. If the existing relay is one of the 'Varley' brand
units with the 15k coil, a resistor needs to be added to allow replacement with the P&B relay.

In the past you could buy a relay contact burnishing
tool Just a flat tool with a coating of diamond dust on it.
These could bring relay and switch contacts back to life
where contact cleaner failed. I don't know if they are still
available and have not made a web search for them. Once a
standard telco item. In liu of these some very fine emery
cloth will work but be careful that none of the residue gets
on the insulation.
If the relay is simply not pulling in check the wiring
and run a bit of typing paper or fine brush between the coil
core and contact assembly.

Hi Garey!
Bingo!
did the cal test and nothing was heard...I carefully removed the relay...took off the cover and cleaned the contacts and then put it all back together....And IT WORKS!!!!

I am so happy......I really enjoy this radio on cw...

Doc -

Your T/R problem sounds like a relay problem. There is one set of contacts that control T/R. The

'arm' is grounded, and the contacts are connected to the XMTR K and RCVR K. When the relay is

closed, the XMTR K contact is grounded, and when the relay is open, the RCVR K is grounded.

First check. When it 'seems to' stop transmitting and failing to receiver, what happens if you turn

on the CALibrator? Tune to the nearest harmonic and see if the CALibrator can be heard. If it CAN

be heard with the receiver still 'dead', then the problem may be the antenna switching contacts. If

you cannot hear the CALibrator, the the RCVR K contact is not being grounded.

If you unplug the relay, the plastic cover can be removed by carefully prying it away from the base

at the center of each long side. There is a small nub. Pry the cover up until it can be lifted

off. Then take a piece of paper and spray or drop DeoxIT on it. Then place it between each set of

contact faces and withdraw with the contacts 'closed'. This should clean them and get you working

again.

First, glad that you solved your problem, Doc. I have been reading your journey closely as I have a TR4C that didn't come back up after storage like I hoped it would. I'll need to take some of the same steps. The rigs are a joy to use.

I caution against burnishing tools, unless it's a last resort, instead Garey's suggestion of some decent bond paper soaked in DeOxit is my preference. This goes back to Navy days, cleaning gold contacts on crypto machines with new, crisp, $20 bills. Wish I would have had access to DeOxit then!! Regardless how careful you are, the burnishing tool removes a LOT more material than a simple drag of bond paper (or card stock) soaked in DeOxit. That contact will fail again, and often soon. Also the DeOxit remains on the contacts and promotes contact long after the "scrubbing" is over. YMMV.

First, glad that you solved your problem, Doc. I have been reading your journey closely as I have a TR4C that didn't come back up after storage like I hoped it would. I'll need to take some of the same steps. The rigs are a joy to use.

I caution against burnishing tools, unless it's a last resort, instead Garey's suggestion of some decent bond paper soaked in DeOxit is my preference. This goes back to Navy days, cleaning gold contacts on crypto machines with new, crisp, $20 bills. Wish I would have had access to DeOxit then!! Regardless how careful you are, the burnishing tool removes a LOT more material than a simple drag of bond paper (or card stock) soaked in DeOxit. That contact will fail again, and often soon. Also the DeOxit remains on the contacts and promotes contact long after the "scrubbing" is over. YMMV.

73,

Don, WB5HAK

Something commonly available now, even at Walmart, is canned air. Many times small grains of dirt lodge between contacts and a blast of air will clear them. If you can get by without chemicals you are better off.

5650. TR-4C low output

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-07-27 17:11:21 UTC
From: w1kilofoxtrot
Topic: 5650 Message: 5650

Just a quick sanity check before I go nuts. Is it possible, or even likely, that V4, the TX mixer, is soft, since I only get good output on 80 and 20? I've gone through and peaked the TX chain as recommended. Yes, I know it's more likely V1 or V3 are at fault, since they form the heterodyne/PTO chain, but I've replaced tubes there to no significant effect.

Have I taken leave of my senses?

73,
Steve
W1KF

Steve -

I would try swapping V3 and V4 just as a check. If no improvement, I would next measure DC voltages
on V1, V3 and V4. Use a VTVM if possible on the Grids of these stages, with the 1M resistor at the
probe tip. If not, stick a 1M on the end of your DMM and scale the readings to account for it.

Date: 2011-07-27 22:05:05 UTC
From: Bry Carling
Topic: 5652 Message: 5652

REDUCED: Box of 70 Precision Wirewound Resistors, NOS.

Most are made by Shallcross Electronics of Collingdale, PA and a few from IRC and Bond Electronics of Summit, NJ etc. Most of these are 1% or better.
Examples: 3.3K, 4.0K, 5.0 K, 6.25K, 23.75K, 50K, 64K, 100K, 130K, 450K, 500K, 900K, 2.0 Megohms, 2.5 Megohms, 4.8 Megohms.
Was $30.00

Will sell the whole box of resistors for $18.00 plus shipping.

73 - Brian, AF4K

OK, so I'm doin' an alignment on a T-4XC and the manual says to set the slugs in the tuning cans to certain heights in accordance with the "dot" color. I see NO dot, but the slug heights I measure tell me I should see a red dot somewhere. I'm guessing there's no dot and it's just WAY out of alignment. If the dot is there, where would it be on the can (L7, L6 etc)? Sorry, I don't have the manual handy right now, but I'm sure you guys know what I'm referring to. THANKS! - Bob

Bob -

I don't think I've seen one with dots..... And I've looked at a lot of T-4XCs! I would expect
it to be a dot of paint on top of the can. Seems like I have seen more than a couple with a color
on top of the slug.? In any event, unless the glyptal Drake used to set them originally is broken,
there IS NO NEED to adjust the individual slugs, just the RF TUNE calibration for the entire rack.

Could the dot be on the base of the can containing the slug? That is where I have always seen them.

Check the hetrodyne oscillator alignment. The HEt oscillator is not used on 80 and 20. Follow the instructions in the manual.

Did that, actually, though I described it as 'peaking the TX chain'. Did not seem to make much difference.

And yes, I understand the nature of the heterodyne oscillator, which is why I mentioned checking V1 and V3. Again, not much help.

I've ordered new crystals, since at least one is way off, and may be part of the problem. Will report back once they get here...

Hello all
Have a problem with a T-4XC. In the 'tune' position the gain control works OK but on transmit with key down I get full power out even when the gain control is fully counter clockwise and the gain control has no effect - up or down.
Would welcome suggestions.
Cheers
Vic

Vic -

Check the ground and continuity on R105 (Front section of GAIN control), and R106, and associated
contacts on S1D(r) (MODE switch). Voltage on the pin of T14 with the coax center conductor connected to it should vary with the GAIN control from 0 to minus ~1.5 VDC.

Well, I decided to re-do the alignment, start to finish, after I installed the new crystals. The combination of new rocks and the alignment seems to have done the trick. I'll try a few CQs and see if I can prove its working!

Thanks to all for the suggestions.

5663. FS: Unique Drake Service Supplement CDs

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-04 21:23:17 UTC
From: Garey Barrell
Topic: 993 Message: 5663

Here is the information that Drake left out of their manuals!

Unique supplemental service information CDs available for the Drake TR-4, TR-4C/Cw/CwRIT, A, B and C
Lines, 2-C / 2-NT and the 2-B receiver.

High resolution color photos of the under chassis and individual PC boards of each unit, with all
parts identified and keyed to a parts list make it easy to locate any component. No more trying to
trace wires through bundles, etc. This information is not available elsewhere and really makes a
difference in servicing these units.

These CDs are NOT just scans of the original manuals that were included with the equipment when new.
High resolution scans of the original manuals ARE on the CDs, along with scans of manuals for
associated equipment such as the C-4, FS-4, MN2000, L-4B, W-4, etc.

All of you who asked for the R-4A/T-4X and 2-C/2-NT, WHERE ARE YOU??

Samples of these pages (at reduced resolution) and purchase information are at <www.k4oah.com>.

I think its better to suck the air out so that you are
not blowing hot air all over the chassis.
I made a very simple arrangement, an AC fan with guard
grills on it and self-stick foam weather stipping from the
hardware store around the periphery. it just sits on top of
the final cage. Keeps the entire chassis quite cool. BTW
this same arrangement works fine on the R4B where I put the
fan over the transformer. I've also made one for my TR-4.
I get the fans locally from All Electronics, they are
also on the web. They are cheap and they have the grills. I
wire them with plain lamp wire with shrink tubing insulation
at the terminals. I use in-line snap switches so that I can
turn the thing on and off conveniently. The particular fans
I got are not noisy. There are ways of slowing down the
noisier ones. The fan does not have to move a great volume
of air to adequately cool the finals and chassis.

My TR-4C has two 4 inch fans on top of the unit. One is directly over the finals, the other centered over the rest. They are 220v, so they are mostly silent, but keep the unit quite cool. They suck air out and blow it straight up, following natural convection. No guards, since they run so slowly...

Mark:
Personally I have always preferred having the fan pulling the hot air out rather than blowing the hot air on through the inside of the unit. That always made more sense to me. I found that using just a very small cpu fan is more than adequate to get the job done.

Hope this helps!
Regards, Donnie

You want to be sucking air out. Blowing air in will only dirty the radio up very quickly which will also act as an insulator to trap even more heat in.

I haven't done the mods to my rigs yet, but I'm told which makes sense, to mount it directly above the PA cage. I have also seen them done on the back of the cage as well which doesn't look so ugly but not as effective as being mounted on the top.

Mark -

A small fan blowing air OUT the back of the PA cage works just fine. A silent computer fan is
great. It doesn't take much, just a gentle fan to get the hot air away from the area. Top is ok,
but requires a higher shelf above the radio, plus some clearance to allow the air to escape.

Sucking the air over the parts that are hot is the best way in this case. However I suggest that once per year you remove the radio from the case and open the final cage to clean inside it. Remove the tubes, then use a soft brush and denautred alcohol to clean the tube sockets and surrounding parts. Clean anything that has evidence of dust build up.

Denatured alcohol with not leave residue or harm parts but don't use any other chemicals because they can. Any radio you use frequently should be cleaned fan or no. Dirt around high voltage can eventually cause trouble and dust or dirt build will retain heat. Drake engineers designed the equipment to work in most any conditions but cleaning one will prolong its correct operation.

Any time you move air, you will also move small dirt particles and other residue which will collect in cracks and crevices around the path of the air. Little dust devils will also form in places that may eventually cause trouble. If you are serious about your equipment and want it to last a long time, then clean it once a year. That schedule will help you remember.

OK Thanks to all, I have a 80mm 12 volt fan I got from Jaycar electronics it will be very easy to mount as it has rubber tabs that line up with the holes on the PA Cage,you just pull them through the holes and they lock on !!!!!!!!

OK on the denatured alcohol { methylated spirits } for cleaning AS I am cleaning it at moment , There is a lot of Greasy hairy sh@#%&**T in PA cage and I am having a hard time cleaning it off ,
The denatured alcohol is not working that well, Maybe some hot soapy water first followed by the denatured alcohol

The Rig works OK but I felt it was not happy in tune up ,I checked the cathode , screen , R26 and meter shunt resistors some were way off, SO just waiting for new one to come
Also for both T-4XB and R-4B I got a capacitor kit from Hayseed Hamfest Co, Grate product and Good to deal with A++++++
I will let the Group now how IT all went after it all goes together with an alignment

Hi Gary
Thanks for reply. Have checked R105 and R106 and they are OK except that 106 is a bit low. Measured from pin 2 V9 to earth and got a
reading of 0-511k rotating R105 from FCC to FC. Haven't checked the v on T14 yet. Hit another problem I have no output at all now. I guess
I must have disturbed something whilst I was fishing around with the Tx upside down. Makes life interesting don't it.

Will try and get that sorted and take it from there.

Cheers

Vic

Vic -

First something is wrong here. There should be 1 Meg from Pin 2 of V9 to ground, unaffected by any
control.... You're not measuring what you think you are measuring!! :-) An ohmmeter from the
'top' of R105 to ground should read from 0 to 15k maximum.

Otherwise, sounds like a ground problem. Have you been through with a screwdriver and tightened all
the ground lug hardware?? That simple, though tedious process can do wonders for 'intermittent'
problems.

The Carrier Oscillator feeds into the Balanced Mixer at 5.645 MHz. The for TUNE MODE, MIC audio
comes into the BM via that coax you're going to check on T14. The MIC amp is converted to an audio
oscillator ~ 1 kHz and the resultant tone goes into the BM for TUNE, like whistling into the mic.
On CW there is no audio, and the same cable is used to feed a DC voltage to the balanced modulator
diodes to unbalance it, and allow the 5.645 MHz CO to pass through. Either case the output goes to
the 1st Mixer where the PreMixer signal comes in at 12.645 MHz (for 7.001 MHz output).

So if you get it back to where you have operation in the TUNE mode, the only difference for CW is
that the 1 kHz tone is replaced by a DC voltage from the R105/106 divider arrangement. Comes
through the same coax as the audio tone. On AM MODE, a fixed DC voltage goes through the same coax
to unbalance the BM just enough to generate the AM reduced carrier. So if one mode works and
another doesn't, you can figure out where to start searching!!

First, check all those ground connections!

Vic -

OK. Still wrong. Pin 7 to ground is R88, the AF GAIN control. You want R105 the XMIT GAIN control which is the 'other' section of the dual GAIN control. One end is grounded, the other end
should measure 0-15k ohms to ground with rotation.

I don't like using denatured alcohol, its ethyl
(drinkable) alcohol with something in it to make it
undrinkable. You never know what the denaturant is. I think
its often acetone. The problem is that the denaturant can be
a solvent for things the alcohol by itself is not, such as
paint.
Isopropyl alcohol (isopropanol) is easily available in

concentrations up to 99+%. It is a fairly safe solvent
although it WILL affect some paints and cellulose based
plastics (like celluloid).
Probably the safest cleaner to use is hand dishwashing
detergent in warm water. For gunk let it soak in for a time.
If its not effective try a commercial cleaner like Fantastic
or Formula-409. These can affect some paints so check using
a cotton swab. If those are not effective I would suggest
trying Kerosene which is, again, fairly safe for many paints
and is a good solvent. After that you have a problem because
more powerful solvents like naphtha, acetone, MEK, all will
dissolve many paints and plastics. Since the cage is
unpainted you have some choice but I would start with the
dishwashing detergent.
Its also possible that a solution of bleach or ammonia
may work depending on what the gunk is.

I've had pretty good success with Scrubbing Bubbles, which I found at my local grocery store. It does a nice job of cleaning out the dust dirt and grime. I haven't used it on Drakes but I did use it on a Swan 500CX chassis. Spray it on and leave it to soak for about 15 mins then rinse off. I used a spray bottle filled with water to rinse the chassis. Make sure you spray and rinse the tube socket pins. I used a shop vac to vacuum the rinse water out of the tube socket pins. I then treated the tube socket pins with DeOxit. That process worked fine for me.

Something similar using Fantastic, which I think is
pretty much the same thing. Vibroplex keys have stamped
labels on the bottom, these cleaners will take it right off.
Not sure that plain water wouldn't. I don't know what
Heathkit used but they may be decals of some sort which will
either dissolve in water or be wiped off. Nothing beats
engraving but it was pretty expensive and even Collins
didn't engrave panels.

I have been following this thread was a good bit of interest, and that presents a question....

My B's run hotter 'n hell.....and the VFO doesn't stop making me run until the boxes get good and warm (Read: Almost too hot to leave one's hand on the cases!)

How much will cooling the 2 components down, with fans, affect VFO stabilization? After all, the B's (at least) were made to run hot.

Garry??

Water is the absolute worst solvent you can choose. First you never know what minerals are in your water. If you must use water, then use deionized. I never suggest water because most people just go to the tap and get it. Around here tap water will leave all sorts of calcium on any surface where it evaporates. Not good for anything especially electronics that contain transformers with cardboard tubes for coil forms. I always have wondered how long equipment lasts after some people run them through a dishwasher.

We don't buy Fantastic here, it irritates our nasal passages, we use 409 which has the warning, "hazardous to humans and domestic animals". What is that? I know it doesn't contain Phosphorus, the label says so. The label also says if you get it on your skin, rinse for 15-20 minutes with water. What is this? I won't use that on my electronic equipment.

Of course if you use any solvent , you should follow good practices. Since I know what is in denatured alcohol, I choose it not some concoction I don't know. Never use any solvent on a painted surface nor on one containing lettering. That is not the thing to do. Always check what you choose on an unseen part of the equipment before you go soak it. Even alcohol. The best practice is read what the contents are of any chemical and follow the common sense approach.

Recently the EPA banned Phosphorus from detergents. I believe you will find they won't clean as well as they should.

Jim/W5JO

Joe -

They DO run hot, especially if under a shelf and/or up against a back panel where the heat can't escape.

Yes, after a long transmission the area over the PA cage can be too hot to touch comfortably. A
very small fan will fix that to where it's almost room temperature. The R-4Bs major source of heat
aside from the tubes is the power transformer. It too can get too hot to touch comfortably after an
hour or so, again especially if it's enclosed at all.

All that aside, I ran these units in RTTY service back in the late 60's, with a small fan behind
each sucking air out of the cabinet and away from the area. A full power (100+ Watts) for 30
minutes keydown was routine. There were three sets, and they all ran 24/7. Aside from the expected
PA softening, (I replaced them when they dropped to 100W output on 20M,) after about two years of
this service, I had only ONE failure, a 12BY7 filament that opened. NO receiver failures, and only
the ONE transmitter failure.

So yes, they DO run hot. It's best for longevity if you can blow the hot air out and away, but I
know of many that ran without fans in normal use for many years. The only heat damaged units were
receivers that lost filter caps and the fuse had been replaced with a piece of copper wire, or
severe abuse of the PA by mistuning, bad filter caps and/or BIAS supply failure, sometimes even when
the proper fuse was in the AC-4.

As for stability, blowing air OUT and away will help stabilize the PTO by keeping a more constant
internal temperature after a short warm-up period, say 30 minutes. Blowing air IN, which some
insist on doing, only forces the hot air, especially in the transmitter, back over the PTO,
including the temperature changes from standby to transmit and back. Definitely the wrong idea!!

Subject: Re: [DrakeRadio] Re: T-4XB Fan Mod

Water is the absolute worst solvent you can choose. First you never know what minerals are in your water. If you must use water, then use deionized. I never suggest water because most people just go to the tap and get it. Around here tap water will leave all sorts of calcium on any surface where it evaporates. Not good for anything especially electronics that contain transformers with cardboard tubes for coil forms. I always have wondered how long equipment lasts after some people run them through a dishwasher.

We don't buy Fantastic here, it irritates our nasal passages, we use 409 which has the warning, "hazardous to humans and domestic animals". What is that? I know it doesn't contain Phosphorus, the label says so. The label also says if you get it on your skin, rinse for 15-20 minutes with water. What is this? I won't use that on my electronic equipment.

Of course if you use any solvent , you should follow good practices. Since I know what is in denatured alcohol, I choose it not some concoction I don't know. Never use any solvent on a painted surface nor on one containing lettering. That is not the thing to do. Always check what you choose on an unseen part of the equipment before you go soak it. Even alcohol. The best practice is read what the contents are of any chemical and follow the common sense approach.

Recently the EPA banned Phosphorus from detergents. I believe you will find they won't clean as well as they should.

Jim/W5JO

Hard water can leave a residue if not wiped off when wet. However, there are many ways of reducing this without the extreme of deionized or triple distilled water. For one thing boiling water for about five minutes and letting cool will remove a great deal of hardness and also dissolved gasses and coagulate any organic matter which will

precipitate as the water cools. Such water is suitable for most photographic purposes. Boiling will also remove chlorine but not the chlroamine used as a modern disinfectant in place of chlorine. However, chloramines _are_ removed by a "Brita" type water filter. The combination of a Brita filter and boiling results in very pure water.

Around here we have fairly hard water. I get an assay once a year from the Los Angeles Department of Water and Power detailing exactly what is in the water.

The labels required by the EPA and others can be quite frightening, however, like MSDS they usually refer to bulk amounts and extreme conditions. Some people are more sensitive than others to the constituents but no one is recommending drinking the stuff. If its irritating, and some cleaners can be, use nitrile (not latex) gloves. That is probably a good idea anyway because any kind of soap or detergent, and most solvents can remove skin oils and moisture resulting in irritation or perhaps inflammation.

There is a good book called "The Dose Makes the Poison" by M. Alice Ottoboni. I have not tried to find it recently but an Amazon search will turn up any that are available. I think it ran to two editions, get the later one. It will give you a practical insight into the real dangers of materials that have scary MSDS.

Different solvents are selective for different things. Some paints are immune to most solvents, some will come off with soap and water. If you don't know what kind of paint you are dealing with you have to test it to make sure you won't damage it.

As far as denatured alcohol, the problem is that very often its hard to find out what the denaturant is. Denatured alcohol may NOT be safe on some materials pure ethyl alcohol is safe for because of the denaturant.

Phosphorus compounds have been frowned on for general cleaning materials for a couple of decades. The most common was tri-sodium-phosphate AKA TSP, which is still available at some hardware stores. This is a quite effective cleaner and forms of it were commonly added to laundry detergents and household cleaners. BTW, is was also used in some photographic solutions because it is a good sequestering agent for calcium and sodium carbonates found in hard water. The problem with phosphates is that when disposed of in the water system they poison fish. For more about this see:

http://www.lenntech.com/aquatic/detergents.htm

There are other sites with more but this is fairly clearly written.

If you really follow out the reasons for banning some materials for environmental or heath reasons you will find that usually the reasons are quite valid. Those who are

inconvenienced often howl about this and blame government for being outrageous but, while government can be heavy handed in enforcement most environment issues are quite valid.

One way of preventing water spotting is simply to blow the residue water off with compressed air. I think I have posted the procedure we used a Hewlett-Packard in the past but its simple so I will post again.
1, Remove any parts which could be water damaged.
2, Rinse the chassis with warm water.
3, Wash out with a solution of dishwashing detergent in a paint spray gun.
It may be helpful to scrub some surfaces with a diswashing sponge or whatever is convenient.
4, Rinse thoroughly with warm water.
5, Blow out as much residual water as possible with compressed air.
6, Bake in a slow oven. We used an electric oven at about 130F for at least 48 hours. If I could I usually left stuff in for a few days.
Usually, the equipment will dry without any spotting or other residue.
Meters and anything made of cardboard or paper must be removed.

Finally, good sense is the first requirement. Sometimes that seems to be in short supply.

From: g4jss@tiscali.co.uk
Topic: 606 Message: 5689

Hello again Gary
Been a rainy blustery day so had another go re the gain on the T-4XC. Hope this clears any confusion I have caused. On the top lug of the
front pot I get 15 - 401K on rotation. On the centre lug I get 0-15.3K on rotation.
I get a zero reading on the pin that the inner co-ax goes to on T14 but neither of my meters are brilliant at the bottom
end of the scale.

R106 is definitely faulty as it only records 10R.

In the tune position with the gain FCC I get the standing current reading set to just below the tick on the meter scale but if I switch to
transmit and key down I have an output around 50w with the gain still FCC. This slowly fades away and stabilizes around 40w.

Will change 106 and see how things are then.

Cheers

Vic

Hi Vic -

OK. Better recheck R106 again... If the front section, (R105) reads 0 - 15k, then R106 is ok.

It sounds like you may have a short in the coax.. With the GAIN all the way up, you should read at
least 1 VDC on the pin of T14 (coax center conductor) in CW, and a couple of volts p-p AC in TUNE
position.

With the MODE switch OFF, measure ohms from that pin on T14. It should read 'open' or infinity in
one polarity. Then reverse the meter leads and you should see a fairly low, (two diode drops)
resistance.

It's also possible that you have an intermittent short inside T14. Those diodes have been known to
touch the shield can, making for a poor short.

Date: 2011-08-07 20:22:33 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5691

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

Hi Garey
To cut a long story short, I have read and re-read R105 106 with analogue and digital meters and they are about correct.
With mode switch off the readings on the inner co-ax pin of T14 are 56.2K and with reverse polarity 49.3K. Switch on and there is no
discernible voltage on that pin in either 'Tune' or CW. You must be brassed off with this (Yorkshire expression) and I am certainly
getting that way!!

Vic

PS. Sorry about mis-spelling your name in previous Emails

From: Garey Barrell
Topic: 606 Message: 5695

Vic -

No problem on the name, I've been fighting that spelling for 69 years!! Thanks Mom..... :-)

Those readings are still a little strange. The circuit, with the MODE switch to OFF, should read
two diode drops either way. The actual reading depends upon the meter's battery, etc., so hard to
put a definite value on it. So it seems like the coax isn't shorted, and it appears the diodes are ok.

The problem seems to be that there is NO voltage on that pin of T14 under any circumstances.

1. Do you get any output in the AM position of the MODE switch? Power on, switch from SSB to AM.
You should see increase in Plate current. If you DO see an increase, measure voltage at the pin of T14.

2. If you do NOT get Plate current in AM, then switch to TUNE and measure the voltage at the center
terminal of R105 as you rotate the GAIN control.

3. Carefully examine S1D(r) contacts and leads.

Remember... 'We do this for fun!' 'We do this for fun!' 'We do this for ....'

FOR SALE: Collection of 38 antique radio dials, knobs and escutcheon scale plates etc.
Includes two large dials for the amateur bands, Some Collins style knobs,
black fluted knobs, chicken head knobs, a large bakelite 0 - 100 knob etc. etc.
Picture on request.
Will sell all for $25.00 plus shipping.

REDUCED: Midland SWR / Field Strength Meter - new in box.
New old stock HF swr meter in perfect condition, shows
relative power and SWR. Also a useful field strength meter for antenna
measurements. A great nostaligia piece too, for those reconstructing their
1960s novice station. Picture on request.
Now available for $15.00 plus shipping

FOR SALE: Box of 30 RF chokes. This assortment includes several 2.5 mH chokes
and others handy for building RF circuits. Two boxes of these available. Picture on
request.
Will sell these for $15.00 plus $6.00 shipping.

FOR SALE: Group of three 40m crystals, type hc6u
Frequencies - 7050, 7072, 7094 kHz
Will sell this group for $19.00 plus shipping

FOR SALE: Group of three 160m crystals, type hc6u
Frequencies - 1801, 1843, 1942 kHz
Will sell this group for $19.00 plus shipping

FOR SALE: Two Drake crystals, type hc6u
Frequencies 24.600 MHz and 31.600 MHz
Will sell this group for $19.00 plus shipping

Thanks for looking & 73 - Bry, AF4K

5697. Drake 4 Series PTOs

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-11 20:46:20 UTC
From: Garey Barrell
Topic: 5697 Message: 5697

It's now official..... The Drake PTOs seem to be 'all over the map' as far as what you might find
inside the can.

I have worked on perhaps a half-dozen in 'recent' times, and ALL were different. Some were 'close'
to the schematic for what they were found in, but more were not.

Now we know that some were replaced by Drake over the years, and apparently they put in whatever
they had on hand. I just opened a PTO out of and marked R-4B, and in scoping out the circuit, the
board is closest to a late TR-4C PTO schematic! It has the output clipping diode, and most values
are comparable to the much later PTO, including the semi-conductors. It covers 500 kHz, not 600 kHz.

I understand it's possible that this is a cobble job, but the linearity and tempco are good, which
'may' be significant.

I would be very interested in any photos of any PTO PC boards that you have occasion to open,
indicating what they were take out of, model and s/n.

Paul -

It is a small box with a coax 'through' it. Inside the box there is a gas filled surge suppressor
from the center conductor to ground, seems like it's a 'C90L' don't recall for sure. The same
suppressor was added across the antenna connector of the later TR-7 and R-7. It's essentially a
calibrated spark gap that breaks down around 90 V.. Obviously it won't protect against a real hit,
but helps to bleed off charges from lightning events in the general area.

Many of the military receivers of the 50's and 60's had a neon bulb right at the antenna connector
for the same reason. I have seen them flash repeatedly if the receiver antenna is connected during
a nearby lightning storm.

That's a "mod" that I like to do with solid-state shortwaver receivers that come to me with shorted front end protection diodes.

Garey,

I am currently in Paris returning home next week. I have six PTO's taken apart that I will gladly take photos and submit them. The genesis of my investigations was the discovery that the 'metal geared' PTO's have an entirely new coil winding that cannot be matched to 'plastic geared' drives. The many schematics from Drake that I have tend to incorporate subtle differences and so far I have found three different circuit-board layouts. By coincidence, I am sure, the most stable of all the PTO's have come out of the RV4C's that I have, which is contrary to PTO mythology. The most prevalent fault causing drift out of specification, was due to moisture absorbed in the coil form causing the geometry to change (slightly) with temperature, or poorly applied varnish around the coil. Surprisingly, I never found a bad NPO capacitor or semiconductor.

NF7Z

Dan -

Cool! That will help a lot. Yes, there are quite a few variations of the 'same' PTO! :-)

Aside from the semiconductor variations, there are at least three varieties, not counting the
TR-4CwRIT/R-7/TR-7/RV-7 version.

The coil is critical, and your observations match mine. MOST that I have found have been 'well
coated' and stable. I've never had to open a metal-gear version, interesting since the gearing only
drives the dial, not the PTO slug.

My understanding is that the highest output PTOs were reserved for the RV-4/Cs to allow for the
cable loss. Their apparent stability may just be a result of fewer 'hot-cold' soaks over the last
40 years......

I've never found a bad t/c cap, but am beginning to find bad Dur-Micas (3000 pF), probably as a
result of 'silver creep'. Again, ONLY 40 years.

Most common has been the Zener getting the 'jitters', and a few cases of 'FET jitters', primarily
in the TIS34 and MPF-102...

I look forward to seeing your data!!

The genesis of my investigations was the discovery that the 'metal geared' PTO's have an entirely new coil winding that cannot be matched to 'plastic geared' drives. The many schematics from Drake that I have tend to incorporate subtle differences and so far I have found three different circuit-board layouts. By coincidence, I am sure, the most stable of all the PTO's have come out of the RV4C's that I have, which is contrary to PTO mythology. The most prevalent fault causing drift out of

specification, was due to moisture absorbed in the coil form causing the geometry to change (slightly) with temperature, or poorly applied varnish around the coil. Surprisingly, I never found a bad NPO capacitor or semiconductor.

5706. Re: [DrakeRadio] T-4XC

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-14 16:52:22 UTC
From: g4jss@tiscali.co.uk
Topic: 606 Message: 5706

Hello again
Re gain problems on T-4XC and your last email. In a.m. mode there is an increase in idling current from just below the tick to .1 on the
meter - in tune position.
In a.m. position get .5v on inner co-ax pin on T14. No voltage in other modes.
On centre lug of R105 no readings at all in any mode.
Re S1(d) it looked a little bit tarnished so gave it a mild treatment of deoxit - still no better. I hope I am correct in
placing S1(d) as the wafer furthest away from the front panel!!

Cheers

Vic

Topic: 606 Message: 5707

Vic -

OK. The problem has to be R104, R105 or R106, or associated wiring, switch contacts, etc.

For AM. the +250V goes through R103 (1M) to a switch tag on S1D(r). The wiper of that switch section goes through the coax to T14. That is working!! The fact that it IS working says that the coax, T14, diodes, etc. are all ok.

On CW, the +250V goes through R104 (2.2M) through R106 (15k) to ground. Simple voltage divider.

The wiper of R105 (500k) connects to the junction of R104/R106. The 'bottom' end of R105 is grounded, and the 'top' of R105 goes to a tag on S1D(r). So what 'should' be happening is that the +250V is divided down to 2.2M / 15k, resulting in a voltage of ~ 1.7 VDC at that junction. Now with R105 in parallel with R106, when the wiper of R105 is at the 'bottom' end, the R106 is shorted and the voltage on the wiper is 0.0V. When the wiper of R105 is at the 'top' end, the 500k of R105 is in parallel with the 15k, essentially no effect. At various points in between the two extremes, 'some' portion of R105 is in parallel with R106, and the rest of R105 is in 'series' with lead to the coax.

So... The voltage on T14 (coax) should vary from 0.0V (R105 full CCW), to 1.69V (full CW). The voltage change will NOT be linear, due to the parallel and series combinations of R105 and R106 at various positions, it will be more of a logarithmic curve. The two forward biased diodes inside T14 will also limit the voltage to about 1.4V max, due to their conducting and dropping voltage across the top portion of R105.

But if you have ZERO voltage in CW, then there is something wrong with a very simple circuit. Most likely is a cracked R104, possibly a short from the R105 wiper to ground, or a bad solder joint somewhere in this area. Of course a bad switch contact could also be involved. Look carefully at the schematic just below and to the right of the key jack. I would measure voltage on each end of

R104, at the top end of R106 w/ R105 full CW. Power OFF and measure resistance from the wiper of
R105 to chassis, should vary from 15k CW to 0 ohms CCW.

From: yash@aol.com
Topic: 5711 Message: 5711

Have for sale or trade, a Drake C-line. R4C,sn# 26645,T4XC sn#26571. Includes a rebuilt AC-4 using the heathkit shop ar4c board. Includes a MS-4 speaker and all new transceive interconnects,all manuals. Includes crystals for all the bands,WARC and some for SW listening. The R4C is just back from Sherwood labs, the receiver HAS ALL the 7 Sherwood Labs mods installed, and working 100%.Sherwood Labs did a complete go thru and alignment. Includes all extra filters,except the AM filter.
Cosmetics are a 9/10,origional paint,faces perfect.All blue led lamps.T4XC,full output all bands.
Everything was just checked by Sherwood labs,no issues of any kind.
selling the last of my drake gear and moving on.
Will consider possiable trades for the C-line:756pro series,746 pro series,Yaesu ft-920, ft-1000/d or ? Looking for hf/6 rig.
will sell the C-line for 1000.00 ,split shipping.
thanks
dale wt4t

Hi Garey
Re gain - I have run into a problem here which I will do my best to explain. For reference I am using a working T-4XC and your CD - board
T10.
On the faulty 4XC R7 has been replaced with two 10K/10w resistors in parallel = 5k and then the wires are lead through to board
T6. If I look at my working 4XC and your CD board T10 one end of the resistor should go to a solder pin (yellow lead)at the bottom right
of the board and the other end of R7 to the bottom left of board T10.Well on the faulty Tx it doesnt. One lead goes to the bottom left but
the other goes to the relay base. I think it is soldered to a pin that has a track running to pin 1 on the relay.

Now if that isn't confusing enough there's more. The track from one end of R104 leads down to where a solder pin should be but comes to an
abrupt end because there is no solder pin there - just a hole. So R104 is not connected to anything. According to the cct dia, your CD and
comparison with my working Tx that is where one end of R7 should be connected - 250v.

What is more confusing is that the Tx did work until this fault developed.

It's bad enough if things are as per the cct. dia!! It's asking a lot but have you any ideas what has been done?

One more thing, have you any diazapam kicking about - I'll pay the shipping costs!!

Vic -

Ouch..... Lemme see if I can follow this.

R7 replacement is fine. I don't have a T-4XC open to look at, but... Pin 1 of the relay IS +250
VDC bus. I 'think' the lower right connection on T6 IS the +250V connection, and if so, then that
is ok as well.

R104 is a little more problematic! :-) ONE end of R104, I think the 'top' end, is connected to
+250V. The 'bottom' end of R104 should be connected to a terminal with a shielded lead that goes to
the wiper of R105. R106 should go from this same terminal to ground. Now, IF there is NO terminal
there, and no shielded lead, then the wiper of R105 'may' be getting voltage from some other
source. Or not! IF just R106 is not connected, it wouldn't have a huge effect on the operation of
the circuit, as the current would still be limited by R104.

As is often the case, someone screws up by 're-engineering' (and I use the term loosely,) to
compensate for a fault, rather than finding the fault.

I'm afraid you're going to have to trace out the wiper of R105, and see where it's connected. From
the circuit behavior, it indicates to me that the 'top' of R105 is NOT connected to the S1D(r)
switch tag. The PO 'may' have made 'other arrangements' for current to the diodes in T14, and THAT
circuit may be what has failed.

I have to admit I have forgotten the original complaint, but the CW GAIN circuit was either not
working, or not working as expected...?? I believe you DID measure voltage at the top of R105?
Might need to refresh! :-)

5714. TR-4C TX kicking out

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-18 16:36:30 UTC
From: William Houghton
Topic: 5714 Message: 5714

Hi all,

I've noticed with my TR-4C that when tuning up (switch in the X-CW position) I can increase the drive to a point where it unkeys itself, goes back into receive, and then keys again. This oscillates at about a 1Hz rate. If I back off the drive it will stayed keyed (as it should). This seems to happen at just higher than 100W of output.

I can't recall if this happens on the dummy load or not. I observed this with an 80m inverted vee with an SWR at the rig of 1.2:1.

Anyone have any ideas what might cause this?

Tnx,

Bill

First thought would be power supply. Increasing drive also increases power supply load. Check
voltages as you increase drive.

Have you rebuilt the ps, (AC-4R or equivalent,)?

Have you replaced the electrolytic inside the transmitter?

Possible weak V2?

Weak V19?

Beyond this you need to check the various signals below to see what is causing the VOX to drop out.

The VOX is tripped and held in by V2 running as a 1 kHz audio oscillator. This signal is the
SIDETONE, and is applied to V19a, then rectified by D5, integrated in C143 and the resultant
positive voltage is used to drive V19b's grid, pulling in the relay.

Hi Garey,

All of my AC-4's have been rebuilt using the AC-4R board (from the Heathkit Shop, I think).

I haven't Hayseed Hamfested the electrolytic on the chassis.

If I understand you correctly, in CW mode (which we use to tune the plate and load), the sidetone osc is turned on and used to drive the vox circuit causing the xmtr to key? (hmmm, very clever !). I presume this doesn't depend on the vox gain and delay controls, or does it? I think I have the vox and antivox control set to min since I don't use the vox on SSB.

Bill

OK, good to eliminate the PS first! :-)

Yes, if the VOX GAIN is too low there may not be enough signal to keep the relay tube pulled in.

Turn it up 1/4 turn or so and see if that does it. If V2 or V19 fall off in gain over time it may
take a bit more signal to drive them.

FOR SALE: Groups of FT243 crystals as used in all the typical ham AM and CW rigs like Heathkit, Drake 2NT, Hallicrafters HT40, etc. etc.

Back by popular demand.

GROUP 01 - (8) FT243 crystals - original ones on
7028, 7038, 7068, 7075, 7130, 7156, 7185, 7196 kHz
Available for just $25.00 total for all eight plus shipping.

GROUP 2 - (8) FT243 crystals - original ones on
7049, 7072, 7075, 7083, 7093, 7130, 7133, 7156 kHz
Available for just $25.00 total for all eight plus shipping.

GROUP 3 - (8) FT243 crystals - original ones on
7125, 7140, 7161, 7222, 7233, 7240, 7247, 7284kHz
Available for just $18.00 total for all eight plus shipping.

GROUP 4 - (8) FT243 crystals - original ones on
7162, 7172, 7192, 7243, 7273, 7277, 7284, 7289 kHz
Available for just $18.00 total for all eight plus shipping.

See lists and buy hrere:
http://www.af4k.com/basementcrystals.htm

Plenty of other ham band crystals on a wide variety of useful frequencies listed here:
http://www.af4k.com/crystals.htm

5720. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-21 21:04:19 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5720

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

5721. Re: [DrakeRadio] TR-4 full power output

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-23 20:58:09 UTC
From: William Houghton
Topic: 5714 Message: 5721

Thanks for the comments on my previous question about the TX on my TR-4C "kicking out". Of course, now that I went to hunt it down, it hasn't done it again. Around the same time I did find that my input cable to my SB-200 which uses an RCA male to PL-259 adapter, practically fell out into my hands when touched.

On the bench is my TR-4. Receiver seems to have basic functionality. When I tried to tune it in cw x- mode I had full power output (100W+) into a dummy load with the XMIT GAIN control having no effect. A meter from the pot wiper to ground shows the wiper voltage changes as its turned. There is a 100-ohm resistor in series with the T-14 can. However, since this point is two diode drops above ground and the 100-ohms is in series with several M-ohms, I'm not likely I think to observe any change in the DC voltage. I did notice that with a scope on the "pot side" of the 100 ohm resistor my gain control would adjust the output from about 40W to 100W+. My guess is that I'm snoopin' in the right part of the radio.

My question to the collective experience of Drake restorers is: it possible or likely that an alignment issue could have the DC balance of the modulator off far enough that XMIT GAIN control would appear to have no effect (i.e- inbalanced enough to cause full output) ?

Thanks & 73.

Bill

Garey,

Okay, I'll give that a try tonight. That would be one of the easiest fixes, ever.

Bill -

OK, good to eliminate the PS first! :-)

Yes, if the VOX GAIN is too low there may not be enough signal to keep the relay

tube pulled in.

Turn it up 1/4 turn or so and see if that does it. If V2 or V19 fall off in gain

over time it may

take a bit more signal to drive them.

Bill -

Is this the same transceiver as below (TR-4C?) or a different one (TR-4?).

What happens in the 'X- AM' position?

How is the carrier suppression in SSB??

There should be '0 VDC' on the wiper of R74 when full CCW. You should be able to vary the voltage
on T-14 from 0 to about 1.4 VDC or so with R74 (GAIN) in X-CW. Bad ground on R74?

From: William Houghton
Topic: 5714 Message: 5723

Nope, different radio. This is a TR-4. This is the one that you like to call a "TR-4B". I don't know the answers to your question since I haven't done anything more that put it in the "tune" mode. I don't want to keep it keyed for too long under these conditions.

I'm assuming R74 is the pot? (I don't have the schematic with me at the moment). I did measure the pot wiper to ground and it did measure from zero to some fairly high value (I don't remember the exact amount) in RECEIVE mode.

I'll check the T-14 voltage.

TNX,

Bill

5724. Re: [DrakeRadio] TR-4 full power output

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-23 22:26:06 UTC
From: Garey Barrell
Topic: 5714 Message: 5724

OK. What serial number? There are 5 versions of the TR-4B.

The only way to check this is in X-CW. As long as the PLATE control is dipped, it won't hurt to
leave it keyed for a few minutes. If you like, set a small fan to blow air across the PA tubes.

In this mode, rotating R74 (XMTR GAIN) from full CCW to full CW should cause the voltage on the
wiper to vary from 0.0V to 'some' higher voltage near the center, then decreasing to about 1.5V or
so at full CW. Pot element possibly not 'connected' internally to ground terminal of pot?

IF you have full output with the XMTR GAIN full CCW, then I would look at the ground on R74.

Also, do you have good carrier suppression on SSB?

There have been instances of the diodes in T14 shorting to the can, which of course destroys Carrier
Suppression.!

5725. Re: [DrakeRadio] TR-4 full power output

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-24 00:48:18 UTC
From: William Houghton
Topic: 5714 Message: 5725

Thanks Garey, I'll try to check it out tonight.

From: Garey Barrell <k4oah@...>
To: DrakeRadio@yahoogroups.com
Sent: Tue, August 23, 2011 3:26:06 PM
Subject: Re: [DrakeRadio] TR-4 full power output

OK. What serial number? There are 5 versions of the TR-4B.

The only way to check this is in X-CW. As long as the PLATE control is dipped, it won't hurt to

leave it keyed for a few minutes. If you like, set a small fan to blow air across the PA tubes.

In this mode, rotating R74 (XMTR GAIN) from full CCW to full CW should cause the voltage on the

wiper to vary from 0.0V to 'some' higher voltage near the center, then decreasing to about 1.5V or

so at full CW. Pot element possibly not 'connected' internally to ground terminal of pot?

IF you have full output with the XMTR GAIN full CCW, then I would look at the ground on R74.

Also, do you have good carrier suppression on SSB?

There have been instances of the diodes in T14 shorting to the can, which of course destroys Carrier

Suppression.!

5726. Drake 4-Line on QRZ

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-24 01:11:42 UTC
From: Dan Galligan
Topic: 5726 Message: 5726

In case any of you might be interested, this fellow seems to have a pretty nice T4X, R4 station for sale on QRZ. I already have my 4-Line stations and don't need another, but I thought many of you would be interested in this Drake Station, especially if you are in the Savannah to Statesboro, Georgia, area.

5729. Re: [DrakeRadio] TR-4 full power output

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-24 16:36:45 UTC
From: William Houghton
Topic: 5714 Message: 5729

I had a little bit of time to look at it last night. BTW, unpeaking the prescaler also lowers the output power making bench testing easier on the finals.

The XMTR GAIN control does adjust the DC bias on T-14 from 0 to 1.74V. The output of T-14 on the scope varies from very close to 0 to about 3.5Vp-p when turning the XMTR GAIN control from CCW to CW. Tonight I might be able to look farther down the chain. I also noticed last night that the symptoms changed slightly. Now I can adjust the output from about 40W to 100W+.

I also noticed that the AGC on receive is misbehaving. Quite often the receiver will have the same effect as if you turned down the RF gain control. A light tap on the chassis fixes it for a few minutes. Are old intermittent radios so much fun ? Perhaps its possible that the two symptoms are related but I'm not sure how.

Bill

Peter Dahl K0BIT SK

Peter Dahl, K0BIT, of El Paso, Texas, passed away August 15 of
Parkinson's disease. He was 71. In 2007 after more than 40 years, he
closed his company -- the Peter W. Dahl Company -- citing health
reasons.

Dahl founded the Peter W. Dahl Company, manufacturers of a wide variety
of custom transformers and reactors for Amateur Radio, as well as
commercial radio and television applications.

Bill -

Have you subbed V13 yet?? Swap with V18?

What band are you working on?? I like to work at 40M, it's low enough to be less sensitive to PA
condition and neutralization, yet uses all stages of the radio. Also, alignment is much broader
here than on the higher bands, again making it less sensitive to minor deviations from optimum.

Check R34 and R40 for value and condition

Yes, subbed V13 if that's the 12AX7A AGC amp.
Doing this on 80m.

Date: 2011-08-25 17:09:50 UTC
From: William Houghton
Topic: 5714 Message: 5733

R32 is up 24% and R40 is up 45% ! Looking at the schematic these are screen grid dc bias ?

Looking at the T-13 output (after the 12BA6) with the XMTR GAIN full CCW we have 480mVpp. The 12BY7A grid has 5Vpp, and the 6JB6 grid has 34Vpp.

Bill

5735. Re: [DrakeRadio] TR-4 full power output

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-25 17:37:17 UTC
From: Garey Barrell
Topic: 5714 Message: 5735

Ah, progress... R32 is just a spur killer, but should be replaced because it's definitely been
abused! R40 is the decoupling resistor for the Driver Plate and is probably a good part of your low
power problem. Typically you'll find ~6 V p-p on the Grid of the 12BY7, so that's about right.

73, Garey - K4OAH
Glen Allen, VA

5739. TR7A Question

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-25 21:11:35 UTC
From: Charles
Topic: 5739 Message: 5739

I checked the VCO as per the service manual alignment item 3.7
and it failed. The High VCO counted to 18,157+ and the lower VCO
went to 33,584+.
Is it possible to set the voltage on this board without extender boards?
In other words, can I just remove the DR7 board and set it or must I have the jumper board installed?
Tnx es 73,
Chuck KA6UUP

First, check to ensure that your +24V supply is good. Failure of the +24V can cause this symptom.

I believe you would need the jumper board installed to make the adjutement, to answer your question.

Ernie,

The real kicker is can anyone identify all the different control knobs.I see a Swan or Galaxy knob, stock Drake knobs but the others are a mystery. The brick/block knob is classic.

I checked pin 2 of the power supply board and got 24.66 volts dc
The service manual calls for 25 v dc.
Is this what you are referring to?
Thanks,
Chuck

>Is this what you are referring to?

Yep. You should be OK there. The next thing to try is to pull the DR-7 board and re-seat it. Oxidized Molex connectors for inter-board connections can also cause your problem. Usually just re-seating the board will fix it, but it's not a bad idea to DeOxit the pins while you are at it. I fought a similar problem in my TR-7 for years - had to leave tthe top cover loose so I could reach in and push down on the DR-7 to make the rig work. After several sessions of cleaning, resoldering, and re-aligning pins, I finally got it to stop.

The Molex pin problems can affect any board in the rig, and it's been noted by myself and others that cleaning and re-seating the boards can solve a lot of odd 7-line problems. Google for the Drakelist home page and go for a search of the Drakelist archive, there's been a lot of discussion there on this topic over the years.

Alan,
The preselector knob on the 2B is much different from the one on the 4 line. The red pointers may be the same, I don't know, but I have all three of the receivers here, and the 2B is the "odd man out". All 2B knobs have chrome inserts.
73, and keep making those knobs!!!!

5756. Drake HF nets

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-08-29 01:07:34 UTC
From: k9sqg
Topic: 5756 Message: 5756

I would like to invite all Drake enthusiasts in the Midwest or East to participate in the Drake nets. The Drake Technical Net meets on Sunday, 2000 hours Zulu, on or around 7238. Experts are on hand to assist with fault isolation, repairs, refurbishing, etc. but not buying and selling gear.

The Drake and Antique Gear Net meets on Tuesday evenings, on or around 3865-8, at 8 pm Eastern time. Buying, selling, swapping, etc. related to tube, vintage, and collectable gear, especially Drake.

Plus there are several other swap nets on HF.

Enjoy that Drake gear!

From: William Houghton
Topic: 5760 Message: 5760

Hi Everyone,

The RF GAIN pot on a TR-4 is giving me grief. This is a dual pot with a switch that provides the AF Gain, RF Gain, and power on/off functions. Does anyone have one in good mechanical and electrical condition from a parts rig?

Checking the schematics that I have it looks like the same dual pot assembly is used on Tr-3, TR-4, and TR-4C rigs.

If you have one, please contact me.

73,

Bill, WA6NEQ

From: William Houghton
Topic: 5760 Message: 5764

Hi Garey,

If it was just noisy, out would come the tube of FaderLube. It seems to be intermittent.

There are times when the rig behaves as if you turned down the RF gain (i.e- the s-meter goes to about 20 or 40 over, background noise decreases, etc). A slight wiggle of the RF gain control "tab" restores things to order. In addition, the volume control has a lot of side-to-side shaft play.

I do have a TR-3 that I haven't bought up to operating condition and I may pull that one out to use in the TR-4. I'm guessing that the AF pot is log taper. Do you know if the RF gain is also log taper?

Bill -

That's a different pot on the TR-7.

Is your RF GAIN pot dead or just noisy or ???

Bill,
This will sound a bit strange, and I don't remember if this applies on the pot in question, but if ANY of the wires go to a PC board, I have solved MANY Drake intermittents on PC board connections by reheating the connection and reflowing them. Over the years, those leads (especially those passing through the board) break connection to the board, and every time something is moved, it rights for a while then goes right back. Same on the rings of control tabs too. These are just getting old (like me) and things like that happen. It may not help you, but surely won't hurt to see.

Also, if you knew the value and taper of the pot, Mouser has a GOOD selection of pots in the 2w version (same size as the old 1/4 to 1/2 w ones). I'm ordering some for my KWM2A this week!!

Ok. Are you SURE there's not a bad ground on the RF pot?

I 'think' the AF is LOG and the RF is LIN. Set to mid range and measure the resistance from wiper
to either side.

Garey,

Nope, I'm not absolutely sure. I'll check it though. I'm still bugged by the "slop" in the shaft so I might swap it with the one in my TR-3.

From: William Houghton
Topic: 5769 Message: 5769

I picked up a 2-B at a garage sale price today. I didn't realize how tiny and cool looking they are! I'm tempted to keep it. Only bad news so far is that all of the xtals are missing. However, I didn't see a xtal socket position for 80m. I was just taking a quick look at the back where it looks like there are spaces for 4 or 5 xtals for the letter positions of the bandswitch and spaces for ham xtals seemed to start at 40m.

Might be fun to bring this radio up.I wonder how well it would do for AM broadcast radio?

Bill -

Imagine the impression it made when the 'good' receivers were the size of a large microwave oven and
weighed 50 - 70 pounds!!

The 2-B is a 'tunable IF' at the 80 M band, so no crystal required. Only three crystals are required to cover the original five HF bands, 11.0, 18.0 and 25.0 MHz. Cheap PC crystals will
'work' if you adapt them to fit.

NOT a good AM broadcast radio. Designed for SSB and CW, IF bandwidths of 3.6, 2.1 and 0.5 kHz.

I was going to use the word "cute" but that doesn't sound manly - hihi.
Ah, nice that its integer xtal freq. By adapt, you're refering to the pin size
and spacing?
No startup issues due to series vs parallel modes, load capacitance, etc when
using PC xtals?

Bill,
I like to liken the 2B to the "Tonka Toys" of the era and a little before. It just "looks like a radio" to me and I have to have one in the shack even if I'm not using it. A kind gentleman that made QSL cards for me in Oklahoma City had one and a CW transmitter I can't even recall, but I can remember him making music with that pair when I would enter his shack!!! Such a sound.

Hi all,

I am working on a nice R-7 receiver and have found that it distorts in SSB on the first word syllable. It is lots worse on M and F AGC settings, but also noticeable in slow setting.

Any hint to solve this problem?. An AGC mod perhaps?

Thanks and best regards,

5774. TR7 Question About PTO and Digital Readout

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-04 01:31:37 UTC
From: Don Cunningham
Topic: 5774 Message: 5774

I am reviving a 76xx serial number TR7 and having a problem that I haven't seen before. It is NOT the 8xxx serial number one that Garey has helped me with several times with a "feedback" in the audio during transmit scenario, this is yet another one that I shouldn't have bought, but it was filthy dirty, on Craig'slist and no one was biting on it, and it was supposedly one owner in good shape, HA HA.

On this one, I thought the readouts or DR7 board were defective, as some segments were unlit upon initial turn on. The unit receives just fine, and transmits fine, so I turned the PTO knob just to see if it changed frequency, and it did just fine. I was going to check another frequency (14.300) as I knew there would be activity and wanted to see if it were on frequency (it's low a bit, but not much). This is the strange part, when I turn the PTO dial, the missing segments would flicker on and off. As I turned it a few times, they started staying on!! Like there is a poor/missing ground in the PTO shaft (like the Drake service note). When the rig is warmed up, they seem to stay on, but I have not had the rig on long term as our daughter came last night for a short visit and I had to discontinue work on it.

Has anyone seen this before, and am I on the right track thinking I need to clean the shaft and add the braid to solve this?? I don't remember this particular issue being a part of that service note, but I have a poor memory anyway, hi. The PTO is much stiffer than most of my other TR7/R7 rigs, but not that bad.

Isn't it strange that so many PTO problems have risen their ugly heads lately??

Don":

I would re-flow the solder on the led module connections to the DR-7. They sometimes develop hairline cracks at the board. I have fixed several that way.

Actually, the first thing with a refurb of any 7-Line equipment should be a clean and DeOxit of all the Molex PC board interconnects. They oxidize over time and can cause some strange problems, and any alignment should not be attempted until you know all the connections are good.

But Peter is correct, incorrect AGC alignment can cause distortion, and the IF gain adjustment is more critical in the R-7 than it is in the TR-7. The AGC alignment procedure for the R-7 seems incomplete, and there have been a couple of attempts published online to try to complete it. I'm still struggling with it a little bit myself, my R-7A still doesn't seem to be "just right", and I wold be happy if I could get the S-Meters in the R-7A and TR-7 to read within a couple of S-Units of each other (two seperate problems, actually). I'm wondering if Bill Frost can offer any wisdom on this.

5778. Re: [DrakeRadio] R-7 SSB audio distortion

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-04 12:10:41 UTC
From: Bill Frost
Topic: 5773 Message: 5778

Hello Jim,

I can't be of much help with the R-7, as I was not on the bench when these were in production, I was behind a desk relying on my technical staff to service those that returned. I don't really recall the AGC causing problems, more failures in the power supply, as it really ran very warm. Lots of complaints about the heat. I fought with engineering on this and got no where. Other than that, we really didn't see to many R-7's being returned for service.

The TR-7 was my biggest concern and problem child. When it was first introduced the telephone rang off the hook, everyone was complaining about DRIFT, the slightest amount of drift was very easy to see with the digital display. And their 4-line didn't drift !!! Those first few months was the only time, I had seeked employment with another company, I was getting beat up on the phone every day. I kept getting told by engineering that "it's the same PTO as the 4-line, it doesn't drift".   I was hired and could have left, but decided to stick it out with Drake, glad I did, as the other company is no longer around (in Miamisburg).

5780. FS: Two Drake crystals $5.00

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-04 16:52:06 UTC
From: Bry Carling
Topic: 5780 Message: 5780

FOR SALE: Two useful Drake Crystals

24.600 MHz and 31.600 MHz - these are in excellent working condition, and will put your Drake 4-line radios on the following frequencies

The 24.6 MHz one covers 13.5 to 14.0 MHz
The 31.6 MHz one convers 20.5 to 21.0 MHz

I only have one each of these. A bargain for smomeone. They are not that comonly used and so they are priced accordingly at $5.00 each plus shipping.

Other drake 2-line and 4-line crystals are available.

http://www.af4k.com/crystals.htm

From: Bry Carling
Topic: 5781 Message: 5781

FOR SALE: Three 160m crystals type hc6u

1801 kHz, 1843 kHz, 1942 kHz

Available for $3.50 each, but makes more sense to take all three for $10.00 plus shipping.

These look to be brand new and unused. Please contact me off the list.

More crystals here:
http://www.af4k.com/crystals.htm

>poor/missing ground in the PTO shaft (like the Drake service note).

There is no direct connection, mechanical or electrical, between the PTO and the display. The display is a preset frequency counter that counts the VCO signal and displays it as actual operating frequency. Peter's comment is the first place to look, but the LED units are getting old enough that they can become intemittent internally as well. In that case, Willi, DF4NW, sells a primo replacement LED display unit using modern devices (whith your choice of color):

Thanks, Jim, Peter and all. I'll, as a matter of course in TR7's, reflow all the solder joints on the readouts and the troublesome "motherboard" connector as well as using DeOxit on the usual places while in there. I have a "stash" of the original readouts that I got in that group buy in the 90's on the Drakelist that John Loughmiller did of the remaining readouts found overseas, but I do know from experience how much of a pain that is to do. I should have a lifetime supply of the red, original ones.

Hi Bill,

Thanks for the reply, and the story! Jeez, don't mention TR-7 drift, or you'll get those guys talking about their X-Lock gadgets again! :) Seriously, I think we are all glad that you decided to stick it out with Drake. What was the root cause of the drift in the early rigs?

I've noticed the power supply heat in the R-7, and have been thinking about adding a small fan to mine. Or, running it from an external DC supply.

Regarding the S-Meter, I noticed that there were several changes to the circuit through the TR-7 life, and into the R-7 as well. Do you have any knowledge of the reasons behind the changes? I've been pondering these issues for a while, and I know that the TR-7 and the R-7 are not "the same receiver" - I don't expect them to perform exactly the same, but it would be nice if they were "close" to each other in S-meter readings of the same signal. Maybe I'm just too picky.

I've been hoping that an R-7 "guru" would chime in. I suppose John Kriner probably has some answers, but he may not want to reveal his trade secrets to the masses.

From: Jose V. Gavila
Topic: 5773 Message: 5787

Hi all,

Thanks everyone for your help on this!. I have realigned the AGC and now it is better, even if not as good as I would like, as there is an slight cracking noise still sometimes on SSB and, on CW, with AGC set on FAST, the effect, as seen on an oscilloscope connected in parallel with the speaker, is very noticeable (as a distorted envelope). MEDIUM and SLOW 'look' lots better.

If I set AGC OFF and reduce RCVR GAIN, all is OK, so it really seems as an AGC problem.

Regards,

JOSE

It might be useful to look at the AGC line with the
scope.

Jose -

There are a couple of AGC setup 'rules'. One just says to set R1127 'fully clockwise' and then
never mentions it again. This is the AGC 'delay' setting, think the -1.34 VDC setting in the 4
series. This is the 'threshold', and the idea is to turn the AGC 'on' just slightly so it doesn't
'step' on , but rather just increases smoothly when a signal appears.

With no antenna, and the IF GAIN (R1138) fully counterclockwise, adjust R1127 counterclockwise until
the output noise JUST decreases. This tells you that the AGC is 'on', just barely.

The reason MEDIUM and SLOW 'look' better is that the AGC doesn't have time to get all the way back
to ZERO before the next syllable comes along.

Maybe someone else has a better explanation, but this is what works for me!

5791. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-04 22:55:20 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5791

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

5792. Re: [Drakelist] [DrakeRadio] R-7 SSB audio distortion

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-05 00:27:27 UTC
From: Jim Shorney
Topic: 5790 Message: 5792

This is where some of the confusion arises. R1127 is called the "AGC Pedestal", and the service manual fails to complete the adjustment, as you describe. The service manual copy that I have says to set R1127 to the center of it's range in the "coarse tune", and the IF gain is left at one extreme if it's setting. If you proceed to the "final adjustmet", this is where R1127 is left "fully clockwise". Someone (I don't recall who, but it should be in the Drakelist archives) suggested that the adjustment to R1138 for maximum audio output, then -3 dB, is a typo and should be R1127. This seems to make sense. R1127 can also be adjusted in a similar manner to R1129 in the TR-7. Although the circuits are not identical, the effect should be the same.

I found a graph at http://www.cliftonlaboratories.com/receiver_agc_curves.htm that shows the AGC knee in the R-7, which seems to be around -100 to -110 dBm. IIRC, this came fairly close to adjusting R1127 via the "TR-7 method" in my unit. The IF gain setting is more critical to proper operation in the R-7 than the TR-7, and too much IF gain will cause the distortion effects that have been described, especially in FAST AGC; FWIW, I have seen at least two TR-7s that had likely been in for factory service, and came back with the IF gain set to max with no apparent issues. My R-7 still seem to be a little too high, I suspect,because the radio still doesn't sound quite right. Too little IF gain will result in a receiver that sounds "deaf" and/or low S-Meter readings, and readjusting the IF gain will probably require the other adjustments to be re-touched.

I'll have to dig through my notes and see what I finally came up with for an adjustment procedure, although my observations are colored by my quest to get the S-Meters to read reasonably close to each other between the TR-7 and the R-7 when "twinned". That may be a pipe dream. Proper adjustment of the IF gain in the R-7 is still somewhat of a mystery. Does anyone know John Kriner well enough to ask if he can shed any light on this subject?

It is important to note also that before any alignment is attempted, the +10V regulator should be spot on. Proper adjustment of the +10V is also critical to proper AGC adjustment in both radios.

5793. TR4C Info

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-06 02:13:10 UTC
From: Don Cunningham
Topic: 5793 Message: 5793

Just a note to help a future person in my shoes today. I took the TR4C that I had bought a couple of years ago off the shelf to play a little radio this afternoon. I had only used it a couple of times then put it back on the shelf to gather dust. I plugged in my AC4 power supply that I know is good (Heathkit shop rebuild) and used weekly on the C Line, turned it on and got a nice receive signal on 20m. I switched to the dummy load, checked the bias (100 mills), then switched to XCW and NADA!!!! No sidetone, no nothing.

Checked the sidetone control on the rear and it was turned off. Tried again, still NADA!!! Let it cook for a while, read the manual again for "rookie mistakes" and found none. Started wiggling tubes just for fun, before getting more serious about troubleshooting (it worked "last time I used it", you know) and when I got to the 6GX6, the receive signal improved to excellent and suddenly I had some drive into the dummy load!!!! Tuned her up, and made many nice contacts. LOADS of fun, with the oldster!!! Got "excellent audio" reports all afternoon on the Shure 444D, then it flaked out and transferred to the 7075 Drake mic, and continued. (I really think I just pulled a wire loose in the mic plug in all the excitement).

Moral of the story, check EVERYTHING when you haven't used a rig for some time. I WILL DeOxit the tube sockets, I swear I will, JUST as soon as I get tired of all these contacts HI HI.

Don:

To add to that great tip...

I have found many TR4-series that don’t receive, including my own when I take them off the shelf. While you’re De-Oxiting the tube sockets give that RX ANT switch a shot on the back lower left side (facing the radio). And put a solder lug on one of the mounting screws to keep the switch from moving, if there isn’t one already – I swear they self-migrate to the Ext RX position through the work of Murphy’s gremlins.

Same thing applies to the OSC switch on the SC-2 and SC-6 rx converters.

5796. Re: [Drakelist] [DrakeRadio] R-7 SSB audio distortion

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-07 02:07:45 UTC
From: Jim Shorney
Topic: 5790 Message: 5796

Here is what John Kriner, via Bill Frost, has to say on the R-7 AGC alignment, reprinted with permission:

Boy, this is a lot to digest. But I'll try to answer the questions as I see them....

AGC pedestal is left all the way CW. I have argued with some folks who claim it must be re-adjusted. But this is the way I have always left it. And the S-meter calibration turns out to be perfect, and S+N/N far exceeds the specifications. 10dB drop in generator level equals an exact 10dB drop on the 'S' meter.

The TR-7 'S' meter can be adjusted for the same exact readings as the R-7. The TR-7 requires some additional 'fiddling', but you can achieve the exact same results without any type of compromise.

The results in the AGC 'F' mode of the R-7 are really normal. I can think of very few uses for this setting, and maybe someone with the smarts could change the T C for more acceptable results.

> I think I just "got it": The IF GAIN is being used to establish the AGC
> pedestal! Does that make sense?

Yes, it does.

Thanks to John for the helpful comments.

73

-Jim

Well, I think I fried my finals.

Yesterday I finally got around to hanging up my latest homebrew G5RV attempt with the hopes it would get me on 80 meters. However, even with my MN4 matching unit, I couldn't get a low enough match. I was playing around trying to tune up the rig into the antenna on 80 for maybe 4-5 minutes.

I may have pushed the finals too much, because now on the other bands I can't get the plate reading any higher than .3 amps and the wattmeter shows only about 100 watts out, whereas before I was usually getting readings of 130 to 140 output.

So what's the consensus, fried tubes or worse?

Bill -

Probably. Messing with an antenna tuner should ALWAYS be done at reduced power. TUNE mode, which
limits the screen current, is best, with the GAIN turned as low as possible while still getting
enough of an indication to determine whether you're making the match better or worse. A good 'rule
de thumb' is to keep the RESONANT plate current down around 150 mA. If the antenna is matched at
30W, it'll be matched at 130W....

Tuning the transmitter into a 50 ohm load in TUNE, then reducing the gain to the minimum as above,
and THEN start twisting on the tuner knobs.

Some start by tuning in a signal in receive, then adjusting various tuner controls for maximum
signal strength to get you 'in the ball park', but I find it simpler to just keep the power down,
and move quickly. This is one good use for a 'modern' transmitter that has a 'fold-back' on the PA!!!!

It would help to know which equipment this is. Also,
are you measuring your power into a dummy load? If so have
you checked the load (most can be checked for DC
resistance). Also check the coax between transmitter and
load.
If you operated the tubes into a high SWR load with
much output you may have overheated them. Most Drake rigs
use TV sweep tubes which do not have much of a safety
margin. If the plates become visibly red even for a short
time its likely the tubes have gone bad. The ultimate test
is to swap the tubes for known good ones.

The dummy load tip is one that should be on here often, and it's such a habit to me that I forget to mention it. ALSO, as cheaply as they can be bought on the used market anymore, an antenna analyzer for HF should become as common as the wattmeter, in Don's humble opinion. I always tune the antenna first with the analyzer, through whatever tuner, coax, wattmeter, etc I will have in line when using the rig. That way it should be VERY close when the transmitter sees it AND I can see bad coaxes, wierd impedances if something is amiss with the antenna, etc.

5806. Questions about TR-3 (worth, etc.)

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-11 23:42:04 UTC
From: yg@internetsmallfry.com
Topic: 5806 Message: 5806

Good evening, all.

I've been into boat anchors for a little while (Hammarlund and Collins, mostly) but I don't know much that's worth knowing about Drake.

I wanted a TR-3 and AC-3 power supply because I'm told that the TR-3 was the last of the Drake transceivers that was all tubes, is that right?

I have a line on a TR-3 with remote VFO and AC power supply for $325, claimed to be in good condition and fully functional, and I am researching to see if that is a fair price. From some of the discussion on this list, it seems that might be a bit high. I saw one photo of the face of the radio and it looked pretty good, but of course there could be lots of dings on the case and corrosion on the chassis and I'd never know that from just one photo of the face.

What do you all think? What should I look for to make it be worth $325?

Also, I'm told that the TR-3 and TR-4 use sweep tubes for the finals. From all reports, many or most of the sweep tubes are rather hard to come by and expensive when found (discovered that in researching a Dentron GLA-1000B a couple of years ago). Are the TR-3 finals, or any of the other parts that should be common (e.g. the other tubes) hard to find?

If I do find a TR-3 at a good price, what kinds of issues and problems that are unique to that radio should I expect to have to deal with?

Thanks to all...

Rick WA1RKT

Rick -

I would advise against the TR-3. It was the _FIRST_ tube transceiver from Drake, and was designed
for mobile SSB use. There is no semi-breakin on CW as in all the rest of the Drake gear, a panel
FUNCTION switch has to be turned from transmit to receive. Of course the only filter is 2.5 or so
kHz wide, again suitable for SSB. The filter(s) also are only four pole crystal filters, so
considerably broader than the eight pole used in ALL the TR-4 series. This also makes it's
compliance with current FCC requirements for 'Purity of Emissions', which is the case with all the 4
Series transmitters. They are all 'grandfathered in', and hams don't seem to pay much attention to
the FCC any more anyway, but if you pride yourself on a clean signal with excellent carrier and
unwanted sideband suppression, the TR-4 is a better choice, for s/n 24000 and up. If you want it
for SSB ONLY it would be 'sorta' ok. It uses 12JB6 PA tubes which are even scarcer than the 6JB6
tubes used in ALL the other Drake transmitters.

The TR-4 is a much better transceiver, but it is still primarily an SSB radio for mobile use. The
CW semi-breakin was added, but still only the SSB filter bandwidth for receiving. The TR-4C is
somewhat better, but really not all that much different. The block diagram is the same, and aside
from the dual dial discs and a light or two, not all that different.

Drake finally added a CW filter (500 Hz) for the TR-4CW, and it didn't take long to realize if you
were going work CW with it you needed an RIT to keep your contact within the receiver passband,
hence the TR-4CwRIT. Of course you could use the RV-3/4 with these, but then you're back to two
boxes anyway, not a very good mobile setup!

Yes, PA tubes are expensive, but have you priced a 'new' 6146 lately?? The 6JB6 IS a horizontal
output tube for TV. They are considerably higher 'perveance' than the 6146, which is one reason
they were chose. What this means is that they draw large plate currents at relatively low voltage,
e.g., 350 mA at 650 VDC, compared with 220 mA or so at the 750-800 VDC of the 6146 based
transmitters. There wasn't really that much difference in the cost of the two tubes back

then, but
savings in high voltage components WERE significant. The very fact that made the 6JB6 attractive is
what makes it easy to 'kill' them with careless tuning. A pair of 6JB6s will draw well over an Amp
of plate current at 650 VDC if operated off resonance. This will kill them pretty quickly. On the
other hand, if you tune carefully, and quickly, and don't try to load the 'wrong' antenna, they will
last for many years. I have 6JB6's that have been in use for over 20 years and still going strong.

For home use, UNLESS you are an SSB only op, you are MUCH better off with any of the R-4A - R-4C
receivers, along with one of the T-4X(any) transmitters. I would recommend against the TR-3 or
early TR-4s if you take pride in your on-air signal.

Feel free to ask questions if I haven't answered them...

Good evening, Garey.

Thank you for the detailed response. I learned a lot just in the last 10 minutes! :-)

I think my inclinations were to either a TR-3 (because it is all tubes) or the latest TR-4 I can find with RIT. Anything in between... doesn't really hold a lot of interest from me right now. Maybe a late-model T4-R4 pair but I've been looking mostly at transceivers so far. I actually don't care all that much if it has the remote VFO... only reason I was considering it is that earlier today I heard of a guy that had a TR-3 / RV-3 plus power supply for sale but I learned this evening that it has been sold anyway so it's moot.

I am planning on this for SSB only. I have four rice boxes (a Yaesu and three Kenwoods) that work perfectly fine on CW, three of the four have built-in keyers, and I also have a Hammarlund HQ-180A and am restoring a DX-100B which will be used primarily for CW... no semi-break-in there! :-)

I'm still working on rounding out my Collins setup (need a 51S-1 or 51J-4 to complete it) and I'm not sure I'm going to have the room or the funds to get into Drake right now, but I do want to do it eventually and I really appreciate you guys being here.

Garey:

*A well composed **synopsis of the differences** between the Drake TR3 and TR4 transceivers. *
*
*
Personally I've* always avoided even the early TR-4's because of the soup can crystal filter. Also even the next series, the version that had the the one piece solid module 6 pole dual crystal filter. *
*
*
*It seems that about 80~90% of the time these earlier versions almost always seem to have at least one or both of the 2 crystal filters that's **gone way off its original designed center frequency thus creating a problem. *
*
*
Personally I never cared for any of the TR4's on CW. Ill take a set of properly working A or B-Line Drake twins any day for CW and be most happy!
*
*
I've* never tried to actually narrow down the serial number breaking points in the TR-4 series that would *somewhat* isolate the different crystal filter versions. I guess *that's* another project for another time...*

These are just my own personal findings of course.

Donnie

Rick -

OK. Well, ALL of the four line equipment has tubes through the RF and IF stages, and up through the
R-4B this goes through the audio (via a single shhhhh SS voltage amplifier, which is one reason you
can listen to an R-4B or earlier all day long without a headache....

There are twelve (12) versions of the TR-4, with each succeeding version have another stage or two
(again oscillators and detection circuits) converted to SS. There is essentially no difference in
the block diagram from beginning to end, with the exception of the CW features. If you are only
interested in SSB, any of the versions 4 - 8 of the TR-4 would be fine. The C offers only the dual
dial to differentiate it operationally. So one in that range would definitely be a better buy. The
CW and CW/RIT versions are identical to the earlier ones, with the exception of the CW features, so
really wouldn't offer you much. Also, since so few of these two models were sold, they have become
quite a bit more expensive than the non-CW types.

My 'newest' radio is a 1985 Kenwood TS-940SAT, which is a terrific radio that does everything I
could want to do. I love it for CW, and have used it for PSK31, RTTY, SSTV, and just about
everything in between over the years. It even 'looks' like a radio, not a DVD or DVR, or
microwave!! BUT, it has no soul. There are NO tubes aside from the display, and there is nothing
to do but twist the knobs. I operate about 95% CW, and prefer my B-Line over the other 18 stations
that I could set up if I had room! Everything from an AT-1 / AR-3 to a 75S-3B / 32S-3. I did sell
my DX-100B and 32V-3, along with the Globe King 500, I just can't haul those big things around any
more. The HQ-129X, HQ-140X, SX-100 and NC-300 are about my limit. I'm afraid I'm still of the
opinion that "If you can't dip the plate, it ain't Ham Radio." :-)

Welcome to the Drake world, and come back any time.

My TR3 works well and I have gotten complements on the audio quality . It's only drawback is that it has three 12JB6 horizontal amplifier tubes which are hard to come by and getting expensive . the TR4 uses the 6JB6 that are easier to locate . also I have found that only the sylvania brand work properly and drake specifies the sylvania brand . there is a 13DE7 , I think , and it is kind of an oddball tube . have never used it mobile even though I do have the DC3 supply . it is rather large for the S10 pickup .
I do not really recommend the TR3 , there are better ones available even if they are hybrids . It is a good piece of american iron .

Ahhh! A REAL boat anchor then! =) I have picked up a couple of older relics that wouldn't be anyones choice of operation today but like them just for the history and "cool factor". I wasn't around to see how Ham progressed but, by collecting a few boatanchors I can kind of witness it some now. Just wished the propogation would let me really go to town.

Understanding a little more all the time on these things. Thanks guys.

God bless

5816. FS: $1.00 ham band crystals

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-14 22:21:21 UTC
From: Bry Carling
Topic: 5816 Message: 5816

FOR SALE: $1.00 ham band crystals etc.
Limited quantities. Please consider buying 4 or more to make the shipping costs worthwhile.

1942 kHz - Type hc6u crystals - QTY 2 available

3547 kHz hc33u crystals (same as hc6u with wire leads) - QTY 10 available

3579 kHz hc33u crystals (same as hc6u with wire leads) - QTY 4 available

7072 kHz - Type hc6u crystal - QTY 1 available

7094 kHz - Type hc6u crystal - QTY 1 available

The above are all just $1.00 each.

Also available:

1835 kHz - Type hc6u crystal - QTY 1 available for $6.00

7050 kHz - Type hc6u crystal - QTY 1 available for $6.00

13.600 MHz Drake crystal - Type hc6u crystal - QTY 1 available for $9.00

Shipping additional for each of these. Combine to save on shipping.

73 & thanks for looking - Bry, AF4K

5817. TR 7. filters 5695 as R4C 1st I.F. ???

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-18 16:47:29 UTC
From: cd40105
Topic: 5817 Message: 5817

Hi, I think this idea may work? although I got the sherwood 600 Hz first IF filter some years ago, I couldn't let a Drake TR7 go to someone else in the U.K. What with a 300 HZ filter at 5695 Khz, I'm hoping this will fit in a 2nd R4C if I can make up a switchable filter
board and relay. I wonder if anyone else has thought about doing this??

73 de ian G3YRQ.

5818. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-19 00:15:13 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5818

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

5819. Relay replacement for TR-3

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-19 02:28:28 UTC
From: joelweder
Topic: 4129 Message: 5819

Hi folks,

I've been cleaning up my TR-3, after pulling it out of storage. Replaced my old power supply with the AC-4 power supply kit. After I proved the rig worked normally, I decided to move on to the TR-4 relay kit. I bought it a few years ago but have forgotten where. (maybe on eBay?)

I've run into a problem with this kit and am hoping that someone else who's done this already might have a thought or two about how to proceed. I am guessing the kit was designed by John Kriner KA8GSP, but the instruction sheet has no contact information.

The circuit board that comes with the kit is supposed to slide down over six feedthrough terminals and sit in the L shaped bracket that held the old relay. (and holds the SO-239)

The problem is that the board is just a little bit too long, or perhaps the hole placement isn't quite right. Once I get the first few feedthrough terminals thru the holes in the board, the board is jammed against the L bracket (near L9) and is still up at about a 30 degree angle.

I can see that the holes need to be maybe 1/8" closer to the relay socket. My options are to drill out the holes (and possibly mess up the traces on the bottom of the board), try to bend the thick and possibly fragile terminals, or try to move the side of the L bracket closest to L9. (which might cause interaction with L9, or at the least the results could be ugly!)

It's been quite a while since I bought this kit but I had thought it was supposed to work with the TR-3. Any thoughts from someone who's done this before would be greatly appreciated!

5821. Drake TR4 cw shift

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-09-26 16:52:10 UTC
From: Juan
Topic: 5821 Message: 5821

Hello,
I have bought a second hand Drake TR4 and I have noticed that the CW rx shift is more than 1 Khz. The sidetone adjust affects your own monitoring but has not effect in the real shift of the trasnmission.
The question is: Do you know if there is some mod or procedure to reduce this shift to a normal level, so to speak 500 or 600 Hz?
Many thanks in advance.
Juan

From: Garey Barrell
Topic: 5821 Message: 5822

Juan -

The CW shift is normally about 800-900 Hz. The amount of shift is determined by C84, which is
switched in series with the 9.0 MHz Carrier Oscillator crystal, shifting it up to ~9.001 MHz, by
closing relay K2. The CO must be shifted by about that amount to move it from it's SSB position
(centered between the Upper and Lower crystal filters) to within the passband of the LSB filter.
The Balanced Oscillator is then unbalanced by a variable DC current controlled by the XMIT GAIN
control on the front panel, allowing the CO signal to increase from it's normal SSB 'null' setting
so it may be amplified as the transmitted signal.

So the amount of shift must be sufficient to get the CO signal past the stop band of the LSB filter,
and into the passband. The amount of shift 'may' be changed by changing the value of C84 to a
smaller capacitance, BUT if you go too far you will lose CW drive as the CO is further down the
filter slope. The ~900 Hz shift was chosen to be 'well within' the passband to allow for various
tolerances in filters, CO frequencies, etc.

Garey:
Seems like I did some experimenting one time and I was able to get to the shift down to about 750 htz before I started to loose noticable drive but that was about as far as I could get by with.

The 1000htz was just too much for most folks on cw and caused too large of a miss match with other cw stations that typically had about a 700 htz shift.

Great explination on how it all works Garey!

Garey:

Seems like I did some experimenting one time and I was able to get to the

shift down to about 750 htz before I started to loose noticable drive but

that was about as far as I could get by with.

The 1000htz was just too much for most folks on cw and caused too large of a

miss match with other cw stations that typically had about a 700 htz shift.

Great explination on how it all works Garey!

Hi Bill -

1. No, the original was a piece of phenolic (brown) tubing, 1/4" od x 1/8" id. The KEY that a lot
of people miss is that the tubing has a lengthwise slit in it that allows it to clamp down. Too
many knobs were destroyed because guys would just keep cranking down on the set screw trying to get
it to NOT slip, with the slit either under the set screw, or exactly opposite it. Donnie, at
<http://2bradioparts.com/page10.html> has an excellent fix, and is probably worth the cost as
opposed to trying to find a piece of 1/4" phenolic rod, drilling a 1/8" hole through the center, and
cutting a small, longitudinal slit !! :-)

Greetings to the group.

Here's a curiosity. I found this website while looking around the web the other day:

http://users.skynet.be/on1cau/k_hussein.htm

The second picture down features the tell tale look of a Drake 7 series station. Definitive proof this was a rig fit for a king?

I guess the King was pretty impressed with Drake gear, and that must have spilled over to his military. They ordered a number of Drake R-4245 receivers (rack-mounted R-7's with built in VRTO like the RV-75) with a very unique olive green front panel colour.

See Sindre/J.M.Cherry's Drake Museum for info. Now if only I could find one!

5830. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-03 00:47:57 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5830

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

5831. FS: Unique Drake Service Supplement CDs

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-03 19:18:23 UTC
From: Garey Barrell
Topic: 993 Message: 5831

Here is the information that Drake left out of their manuals!

Unique supplemental service information CDs available for the Drake TR-4, TR-4C/Cw/CwRIT, A, B and C
Lines, 2-C / 2-NT and the 2-B receiver.

High resolution color photos of the under chassis and individual PC boards of each unit, with all
parts identified and keyed to a parts list make it easy to locate any component. No more trying to
trace wires through bundles, etc. This information is not available elsewhere and really makes a
difference in servicing these units.

These CDs are NOT just scans of the original manuals that were included with the equipment when new.
High resolution scans of the original manuals ARE on the CDs, along with scans of manuals for
associated equipment such as the C-4, FS-4, MN2000, L-4B, W-4, etc.

Samples of these pages (at reduced resolution) and purchase information are at <www.k4oah.com>.

Hi, as theres a mod for the TR7 vfo with the cumbria designed X-lock, One would be seller of a TR7 tells me even with the heat from the P.A transistors, it should not be a problem?? I'm bit dissapointed with the vfo drifting off frequency..maybe the set needs to be switched on for a longer period of time..but I question this though I may only run at at a lower power O/P. I need to get to grips with this problem before
getting involved with PA0KSB type frequency stabiliser..73 ian g3yrq.

5834. Drake RV4C, some simple questions

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-05 16:30:36 UTC
From: billykatzz
Topic: 5834 Message: 5834

I finally got my hands on a RV4C unit and it looks to be in pretty nice condition. I haven't tried hooking it up to my TR4Cw yet, but have a few questions, just cosmetic and mechanical:

The two horizontal "grills" look a little pushed in. I'm supposing this is a pretty common condition of many of these units, as the grills are unsupported and, after all, are aluminum sheet metal. Any cautionary information about trying to straighten them out?

The PTO dial turns a little more easily than my TR4Cw unit. I understand there's a way to add some resistance to the turning mechanism. Can anyone walk me through the procedure?

Ian -

Are you using the FA-7 (or other) fan on the TR-7?? It doesn't 'need' the fan for cooling the PA
under normal operating conditions, but the internal temperature of the unit is much more stable with
the fan, blowing OUT.

The TR-7 uses an analog PTO, essentially the same circuit use in the 4-Line system. So it will NOT
be as stable as modern, synthesized radios, but will also not have the phase noise present in most
of those. I believe the spec is 'less than 100 Hz after warm-up', which is the same as the 4-Line.
I read this to mean that it will stay within +/- 50 Hz over time. I recently had a 4-Line PTO on
the bench, sitting out in the open, and it easily stayed within that limit, UNTIL the A/C came on
and blew cool air directly on it, when it moved by about 150 Hz.

If this is insufficient for your needs, then the Cumbria X-Lock is an excellent option. It is not
particularly difficult to install and works quite well. Another option, considerably more expensive, is the RV-75 external VFO. It is synthesized, and is just as stable as today's radios,
at the expense of some phase noise.

I don't know about the grille problem. Shouldn't be difficult, unless the fastening around the
edges has NOT let go. If the edges are solid, then the grille material has stretched, and I don't
know how you fix that.

The only 'safe' way I know to tighten up the tuning is to use a heavier grease on the bearing and/or
lead screw. Some suggest just over tightening the rear bearing, but this overloads the bearings.
The adjustment should be made only as tight as necessary to eliminate any side play in the front
bearing. This is the Allen screw adjustment accessible from the rear of the PTO gearbox when the
PTO shield cover is removed. Some covers have an access hole in the rear wall, but trying to do
this adjustment by sticking the wrench in there is a good recipe for disaster. Much safer to remove
the cover and SEE what you are doing.

Nye lubricants sells damping grease in several grades.
Its possible that some of the right grease in the right
place would give the dial the feel you want. Damping grease
is used, for instance, on the focusing threads of lenses.
Nye sells their stuff retail through another company
but I don't have the link on this machine.

If you are using the PLATE meter on the TR-4, -OR- an average reading (most) wattmeter, 20-30 Watts
is about right. A scope or peak reading Wattmeter should read about 100W. If you just whistle a
steady tone into your mic, you should be about 100W on YOUR meters.

KE9PQ is a good source for the mic plugs, either straight or right angle. They're called 3/16" or
0.206" dia phone plugs.

Thanks Garey for prompt reply. I guess all is well with the radio...I just did a lot of changing in station and going from FT 840 and an AL 80-B,,,,I expected too much on lower bands...My meters use average or peak...so, hey at least I know I'm tuning the old girl up right...tnx agn...it performs as you said....73's de HXB.

If you are using the PLATE meter on the TR-4, -OR- an average reading (most) wattmeter, 20-30 Watts is about right. A scope or peak reading Wattmeter should read about 100W. If you just whistle a steady tone into your mic, you should be about 100W on YOUR meters.

KE9PQ is a good source for the mic plugs, either straight or right angle. They're called 3/16" or 0.206" dia phone plugs.

wd5hxb wrote:
> My TR 4 will dead key 100 watts but the old General Electric mic, or some other cause will not produce over 20 watts on SSB...all on meters not antennas. Want to wire in an old Turner Plus 3, any problems with that? Also, any source for another mic plug for the TR?...Or maybe I'm to old to mess with this thing. Could be sold but I think I'd want too much for it, matching speaker with power supply built in...I think the market has hit a low for these things....help with the wiring (I think I have that down) and advice on the Turner plus a source for another plug would greatly be appreciated...thanks...de HXB.

The +3 is a good sounding mic - basically a Drake 7075 is a +3 without the preamp. Strictly speaking, the preamp is not at all necessary for your radio, but it is a compressor amp that actually does a decent job. I hooked one up to my TR-7 on a lark (I generally despise preamped mics) and often get unsolicited compliments on my audio. In checks with locals who know my voice, the +3 was preferred over a Drake 7077, Shure 444, non-amplified D-104, Turner 254HC, and ElectroVoice 729 - although it was almost neck-and-neck with the 254HC and the 729. YMMV, depending on the characteristics of your voice.

5844. Where to connect loose wire

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-07 17:55:40 UTC
From: dr7zyq
Topic: 5844 Message: 5844

I have a TR-7 which has operated well until now. I turned it on yesterday to find that the display is out -- but that isn't what this is about.

I opened the radio to deal with the display problem and there is a single wire with lavendar colored insulation coming from a push on connector next to the speaker, which lavendar colored wire is no longer attached to the circuit board. I know it used to be, but cannot locate the place where it must have broken loose.

I need some guidance on where to reattach that wire.

I don't have the service manual and the op manual doesn't even have a photo of the circuit board to give guidance.

Thanks,

David, WA7ZYQ

Just what I needed. I had figured that it must go there -- that was the vicinity I remembered it being in -- but it didn't leave any residue to verify that. Now I can reattach and get back to dealing with the first problem.

Many thanks,

David, WA7ZYQ

5850. PS-7 Supply

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-08 02:16:24 UTC
From: Ed WA4NJY
Topic: 5850 Message: 5850

My PS-7 is doing fine but I wonder if some components should be changed out to avoid problems later.

Do I need to worry about regulator circuits allowing voltage to rise, etc?

Thanks,
Ed WA4NJY

It would appear so, since the pic I sent was a crop of that area of the board
from a service manual pic.

Make sure the regulator IC is snug in it's socket, and the pass transistor screws haven't loosened up. Inspect and re-seat other connections as necessary. Install the optional fan, if it doesn't have one. The main filter caps may eventually fail, but no sense replaceing them if they are still good. The PS-7 is pretty much bullet proof, no need to tinker with it. The only known mod is a bypass cap on the auxiliary 12v output. Some PS-7 notes here:

http://www.alg.myzen.co.uk/radio/tr7/mods.htm

>Do I need to worry about regulator circuits allowing voltage to rise, etc?

There is a crowbar circuit built in to the design to protect the radio from overvoltage.

David -

Hard to say exactly what it is, BUT, there should be a wire connected to Pin 1 of U9002. If no wire
there, that's probably it!

Looking from the front panel down on the DR-7 board, left corner nearest to the front panel, the
first IC along the left edge of the board is U9001. The one just 'above' it is U9002. Pin 1 is the
first pin on the top right corner, where the 'dimple' in the IC package is. You'll probably find a
strand or two of wire still there if no wire.

Thanks, Garey. That confirms what it looked like from the photo that Jim sent, and I appreciate that. I've seen that wire so many times before, but couldn't pin down exactly where it went.

I have a pdf of the service manual but the photos are illegible. Maybe I should spring for the real deal one of these days.

Oh -- and a very clean break. No clues at all.

Glad that was it.... A service manual can be very handy! :-)

You might check with WB3CEZ. He was selling a very clean scan of the TR-7 Service manual on CD for
$10. I have one, and I use it as much as the paper version I have. He usually sells on eBay, but I
don't see a listing at the moment. An email might do it.

5856. Re-capping an R-4

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-08 15:10:47 UTC
From: Lee Hiers
Topic: 5856 Message: 5856

Hi folks,

I picked up an R-4 (no-suffix) about a year ago and listened on it for a while with just a random wire inside the house. Really like the radio. Back in the spring, it developed a hum, and sounded like the radio was zero-beat with a carrier wherever I tuned. I figured filter caps were bad, and probably something in the AGC circuit. I subsequently got married, moved, etc. and figured the repair would have to wait until things settled down a bit.

I'm finally getting to where I can look at the rig. I opened it up, and it looks like it's never been touched inside. So, I decided to get a Hayseed can replacement for the filter caps instead of going with discrete caps. Mine has a three section 100mfd/200v can - not the 4 section Hayseed sells as a replacement. No problem, just use the three 100uF sections, ignoring the extra 22uF section.

Anyway, to the point... There are about a half-dozen or so paper caps in the rig - should I routinely replace them as well? If so, any particular recommendations?

I'm also planning on replacing a few tubes - in the RF am and AGC stages for starters. Any pitfalls to watch out for there?

Thanks!

Free PDFs off the internet usually aren't very good. People were either too lazy to take the care to make a good scan, they were done on a cheapo scanner, or they were created the day when it was critical to keep the file size down. The photo crop that I sent was from the PDF on the HAManuals CD, which was one of the first CDs out there, and it's very good. You get what you pay for. I also purchased a very good hardcopy repro from an eBay seller who later offered it on CD as well, it may be the same fellow that Garey mentioned.

C90A wasn't used until the late R-4B. It was probably used in the first prototype of the R-4, but
the first R-4 schematic (0001) showed only C90B, C and D. I guess Drake just got a good buy on
four section caps.!

Drake used good quality epoxy 'film' caps, and I don't think I have found a bad one yet. Of course
the tubular electrolytics should be replaced in the BIAS and AF OUTPUT Cathode bypass.

The most likely problem in the AVC circuit is gassy 12BA6 IF tubes. They cause the S-Meter ZERO to
drift among other things.

When you price out a 12BZ6 RF AMP tube you may want to make the mod made by many when the R-4 was
'new', i.e., move a filament wire and use a 6BZ6 instead. The 12BZ6 was expensive and hard to find
even back then.

Beyond that, we're here!

Lee,
You will get several different answers on these questions, but I'll give one response, hi. I wouldn't hesitate to replace the paper caps with some good Orange Drops or equivalent cheaper ones. The new ones will be smaller and higher voltage which won't hurt.

I would NEVER change tubes out "just to be changing" them, instead use the new ones to exchange with the old ones if you feel one is not working for some reason. The alignment of the rig was likely done with those tubes, and different ones will act differently in the same circuit. I would spend my time loosening and tightening the scews that give the grounds in the unit (all of them, hi) and cleaning contacts with DeOxit and think the time to be better spent. You can replace defective tubes as needed later.

As I said, each user has a different slant, but that's mine and I'm stickin' to it, hi.

The hard copy is from Mark at <http://www.ke9pq.com>

It's $20 plus shipping, and a VERY good scan with full size (fold-out) drawings.

That may be it. Primo stuff, no taped-together foldouts or reduced size pages.
This is the real deal, almost as good as a Drake original. In fact, I do have a
Drake original, but I use the repro for all my "heavy lifting".

Garey,

Is there a way to better distinguish between the black-plastic paper caps and black-plastic film types? I'm sure I unnecessarily changed out a few caps in my R-4B, and perhaps the R-4C thinking they used paper dielectrics.

Paul -

The (mostly black with white fill, yellow or white) film caps have the solid epoxy fill at the
ends. They look like they were just turned on end and filled with liquid epoxy that flows around
the wire lead. They may well be paper dielectric, but are so well sealed that it doesn't make any
difference. The so-called 'black beauties' were made with two half-shells that were glued together,
leaving a poor seal at the leads. So oil can escape and moisture can get in, causing failures.

The only Drake caps I have found bad were ones that had a soldering iron laid up against them,
melting the tube, or where the leads had been yanked hard enough to crack the end fill. Any that
'look' good are 'almost' always good.

Don -

Good points. No it certainly won't hurt to replace the caps, but those awful orange radial lead
caps just don't 'look' right! :-)

Definitely agree on the tubes. 'Replacing with all new tubes' is a waste of money AND tubes. The
only tube I find that need replacing are the 6/12BA6's in the IF, just had another one (buried under
the shield, NB and NB bracket of course!) yesterday in an R-4C. S-Meter ZERO was against the stop.
Occasionally I'll run into a bad 6EH5 where the Cathode bypass cap has shorted, or once in a great
while the RF AMP will be a little weak at 10M. Of course the 3rd Mixer in the R-4C is sometimes a
problem, and I have to find a 'good' (quiet) replacement, but fortunately I don't do too many "C's"!!

DeoxIT and tightened screws 'fix' a multitude of problems. I just had to get a new bottle of
D100L. Ouch!

Yeah, it's painful all right..... seems to be 'price controlled' at $25. I have Amazon 'Prime',
so no shipping charges and got it in two days. There may be someone with it on sale, but you don't
often find D100L on sale and my time is worth 'something'! :-) The good news is that it lasts
for years! :-)

Don,

I recently made a purchase of the 2.4 ml bottle for $15 through Amazon. I combined it with some other solvents and shipping was free.

I've stopped using DeOxit on wafer switches and now pretty much limit its use to pots/faders. I have not had any trouble with DeOxit on wafer switches, but I've seen evidence of the dirt/dust it attracts over time.

So now, I'm using several fast-evaporating Chemtronics sprays and the results have been just as good as DeOxit on open switches. For example, I recently purchased a Collins 75S-3C and the band switch was so intermittent, I thought it was broken. I used the Chemtronics spray developed for switch contacts and the bandswitch operates like new.

Does this stuff leave any lubricant behind, or do you just get metal-on-metal when it's done?

Jim,

Good question. From the Chemtronics datasheet, it states:

"Leaves protective hydrocarbon lubricant"

Whatever lubricant that remains does not stay wet over time like DeOxit -- unless Caig sells an evaporating form of DeOxit?

Good info, Paul. I cringe when I think of how many un-lubricated switches and pots must be out there becuase people have cleaned them very well. :)

Don,

I recently made a purchase of the 2.4 ml bottle for $15 through Amazon. I combined it with some other solvents and shipping was free.

I've stopped using DeOxit on wafer switches and now pretty much limit its use to pots/faders. I have not had any trouble with DeOxit on wafer switches, but I've seen evidence of the dirt/dust it attracts over time.

So now, I'm using several fast-evaporating Chemtronics sprays and the results have been just as good as DeOxit on open switches. For example, I recently purchased a Collins 75S-3C and the band switch was so intermittent, I thought it was broken. I used the Chemtronics spray developed for switch contacts and the bandswitch operates like new.

Garey,
Where did you find the D100L DeOxit?? I need to get a bottle (even if it hurts) as I am getting stocked up to do a BUNCH of rigs this winter. Hope my ambition holds out. I've been helping Hayseed's sales, HI.

I've not had any problem using the D100L liquid on switches. i don't pour it on, just a drop with
the needle applicator and work it through. I do NOT use or recommend the Q-tip / silver polish,
etc. approach favored by some. Too much chance of hooking a cotton fiber on a fixed contact and
springing it or other physical damage. I don't care if the rotors are black with silver oxide as
long as they have that pretty little stripe of silver down the middle! :-)

The D100L bottle that I got is 25 mL with the needle applicator.

Where do you find the Chemtronic stuff. I generally don't like sprays for anything, too hard to
control where they go. If it leaves no residue that means it also leaves no lubrication, which can
kill a rotary switch. I'm always amazed at the difference DeoxIT makes on something like a
bandswitch with 6 - 8 sections. They go from 'can't hardly turn it' to 'smooth as glass'.

The only spray I use is the FaderLube from DeoxIT. It works great, and you're spraying INSIDE the
pot. It apparently has a heavier lubricant than DeoxIT liquid because the pots become nice and smooth.

Garey,
Which strength of the Faderlube do you use, the 100% like on DeOxit?? Through Amazon the company "Micro-Tools" has the complete Caig line at decent prices, and I think I'll get some of both DeOxit and Faderlube. Have an audio pot on my KWM2A that needs a shot, hi.

HI Group
I have a L-4B and PS The cable that goes from the PS to the AMP is very short ,I want to place the power supply under the bench is there a longer cable available for them, about three foot ??
or could I make a new cable ?? Is there any issues with making a longer cable ??

IF I made one I don't know what to use for the HT lead in the cable ?? The original one look like Teflon insulation ??
Any ideas on this matter
Thanks Mark VK2MTB

5883. Drake R7 & Matching speaker

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-11 02:46:39 UTC
From: _
Topic: 5883 Message: 5883

I have an R7 and matching speaker that I plan on offering for sale in the near future. It is on the bench now being checked out, it and the speaker appears to work to factory spec. There may be a few minor blemishes on the cabinet but I dont remember seeing any major scratches, dents or dings.

Question.. what does an R7 and matching speaker go for these days on the used market?

Thanks for any help

Jim

Look here:

http://www.wb4hfn.com/DRAKE/DrakeSalePriceHistory.htm

Price is dependant to a degree on options and filters installed, so it is
imortant to list everything in the receiver.

The list has not been updated in over a year. I would suggest that due to the economy the prices have changed somewhat. Except for the best of the best.

R-7s seem to hold their value well, regardless of the economy. An R-7A fully decked out with filters and NB just sold on the 'bay on Oct. 8 for $1227. I would expect a fully loaded R-7 to sell somewhere around the middle of the range listed for that model.

5890. CW on TR7

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-12 03:04:55 UTC
From: Brenton Crowhurst
Topic: 5883 Message: 5890

Dumb question, I apologize -- it tells you how much CW I'm doing, but I'd like to do some more.

So, my TR7 manual tells me to tune in a signal for around 800hz tone . . . the transmit signal will be offset by 800hz, so no need to actually zero beat on the receive signal.

And my question is . . . ahhh, which direction is the offset? If I do, in fact, zero beat on a signal, I can hear him just about as well on one side of the null as the other.

Not knowing how to properly use this rig has left me, so far, only to call CQ on CW.

Thanks in advance.

Brenton Crowhurst,
VE6IE

>And my question is . . . ahhh, which direction is the offset? If I do, in fact, zero beat on a signal, I can hear him just about as well on one side of the null as the other.

This should not happen in normal operation. When receiving CW, the TR-7 is "sort of" in USB mode. You may hear some signal on the other side of zero-beat, but you shouldn't hear much.

>Not knowing how to properly use this rig has left me, so far, only to call CQ on CW.

You should still be getting callers, unless your fixed passband adjustment for CW is too far off. Try it with PBT set as for USB. The confusion with the TR-7 usually arises from a subtle difference in the way the radio operates as compared to many "import" radios, and only when you are looking for someone on a specific frequency. The TR-7 shifts the TRANSMITTER DOWN in frequency, with the dial reading the RX frequency. The "other" radios shift the RECEIVER UP in frequency, with the dial reading the transmit frequency. It's easy to completely miss the guy you're looking for on a specific frequency, especially if you have a narrow filter switched in. With causal tuning and calling, it's usually not a big deal.

Where it gets complicated is when you run across one of the older rigs that uses sideband inversion to cover the lower bands. You can end up way off from where they think you should be. But that's not a problem that's specific to the TR-7.

Jim is that pretty much the same for the TR-7?

Could you be a little more specific with your question? There's a lot in the post you quoted. Quote trimming would have helped...

Yes, about 800 Hz with the RIT off or centered. You can use the RIT to tailor the offset to your liking, or actually adjust the frequency of the offset oscillator on the 2nd IF/Audio board over a limited range.

Side note: K8AC's article on key clicks in the TR-7 at http://www.wb4hfn.com/DRAKE/DrakeArticles/TR7_Key_Clicks.pdf is an excellent contribution to the art. I followed Floyd's guidelines in the article and tweaked my TR-7 into a near-perfect CW keying waveform.

5896. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-16 21:14:12 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5896

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

Hi folks...

Just to, uh, recap...

I replaced the can cap along with the two electrolytics included with
the Hayseed kit. That completely took care of the hum, naturally,
and, happily, the apparent AGC problem. I picked up a 12BZ6 along
with a couple 12BA6s, but no need to change 'em. I now have spares.
;-)

I'll have to wait to check the rig out on the higher frequencies, but
it's doing great on 40/80/160 now and that's where it's going to spend
most of its time anyway!

Next step: get the Heathkit DX-40 up and running!

Thanks to all for the help.

5898. strange hookups on R4B

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-19 02:44:17 UTC
From: dtompsett
Topic: 5898 Message: 5898

I'm playing around with an R4B that was passed along to me. Previous owner definitely didn't do these mod's.

On the back cover there are 2 extra 'rca' plugs... one in the 'spare' hole (labelled "Scan"), one on the opposite side, between accy power and inj. plug (labelled "Mon").

"Scan" is hooked up the V2 using some old coax... shield is soldered to ground at V2-2, center pin is soldered to small cap (12+/-5em) on V2-5.

"Mon" is hooked up much the same way to V5. IIRC it's the same pin connections.

What would these be for? This mod looks OE... cap's are same style and appear to be the same vintage as other's in the rig. I checked the wiring diagrams and they don't appear to be anything original on those tube socket connections.

Would a picture help?

I notice a few pics online of other R4B's with a socket in the 'Spare' location... like here at AI4FR's site... http://www.ai4fr.com/main/page_ham_radio_drake_r4b.html

Any insight would be appreciated.

5899. Re: [DrakeRadio] strange hookups on R4B

From: Garey Barrell
Topic: 5898 Message: 5899

I don't know of any 'almost official' mods of that sort.

They sound like pick-off's for a 'band scanner' (V2) after the Preselector and before the roofing filter. This would be a good place to hook up a panadaptor such as a Softrock, etc. The one on V5 is after the Passband tuner and so would see only the output of the IF filter bandwidth chosen, essentially where you would attach an 'alternative' detector/audio system.

The 'spare' holes on the transmitter were intended to be used with the modifications needed to operate with the VHF accessories (TC-2, TC-6 and CC-1 with crystal controlled converters,) a 'sample' of the 14 MHz RF. The ones on the receiver are often used for attaching a scope to monitor modulation of received signals or things like your receiver was modified for.

Unless you plan to use them, I'd pull them out and re-align.

From: fred
Topic: 5900 Message: 5900

got a puzzle .
tuned it up on 3873 for the traffic net and the swr metre showed 1.5:1 with 110 watts out .

without changing anything except the main tuning dial I went down to 3870 for the BA net , swr was down to the point where the metre would not even read anything and the power out was up to 125 . is that a normal behavior or should I be looking for a problem ?
transceiver is working well .

What's your antenna? Is there a tuner between it and the TR-3?
It might be instructive to plot swr over a wider portion of 75.

no tuner , adjusted dipole for resonance at 3900 and swr is under 1.8:1 from 3865 to 3935 . dipole is 120' of #12 thnn . coax is rg8 , no balun
the FT950 works well on it too without using the internal tuner .

I would say that a change in SWR (Standing Wave Ratio of Forwrd power to Reflected power) from 1.5:1 to 1.1 to 1 means that there would be more forward power observed. This tells me that your antenna is tune rather sharply and is not very broadbanded if you see that mnuch difference with only 3 kHz shift downward in frequency. It also tells me the antenna is more resonant at 3.870 than it is at 3.873. You should try doing down to 3.850 and tune up and check SWR at that frequency. You'll more than likely be up again at 1:5 or greater to 1.
I don't think there's anything wrong with your rig.

I believe that Bernie is likely right. Your antenna is likely not very broadbanded, and is about perfectly tuned to 3870khz. If you are in doubt, or have reason to think otherwise, try a different radio, tuned to those two frequencies, and check for similar results. But, I imagine the result would be about the same.

From: Garey Barrell
Topic: 5900 Message: 5907

Looks typical.

You DID retune the TR-3 each time you moved the frequency?!?

Don't forget that Forward power indicated will INCREASE with increased
SWR. SWR is calculated by the RATIO of indicated power between Forward
and Reflected.

>> I would say that a change in SWR (Standing Wave Ratio of Forwrd power to Reflected power) from 1.5:1 to 1.1 to 1 means that there would be more forward power observed. This tells me that your antenna is tune rather sharply and is not very broadbanded if you see that mnuch difference with only 3 kHz shift downward in frequency. It also tells me the antenna is more resonant at 3.870 than it is at 3.873. You should try doing down to 3.850 and tune up and check SWR at that frequency. You'll more than likely be up again at 1:5 or greater to 1.

5908. Drake RV4C, removing front knobs

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-21 20:48:26 UTC
From: billykatzz
Topic: 5908 Message: 5908

I'm thinking about doing some slight cosmetics to my recently acquired RV4C remote VFO, in particular getting the grillcloth flush to the front (it's a little "sagg-y").

I've pulled the unit from the case and see the front panel is screwed to the chassis and that it appears I'll have to pull the knobs in order to access the grill cloth. The one reservation I have is the main tuning knob with the alignment skirt. Is there anything I should be aware/cautious of when removing the tuning knob?

From: bpierfel
Topic: 5909 Message: 5909

Anyone have opinions on improving the R-4B's distortion prone product detector with an active device like the SA-612 / NE-602?
I believe Sherwood sells a kit, anyone try it in an R4-B?

Seems like I recall reading somewhere on using HP hot carrier diodes to improve performance. Anyone done this?
tnx

Bob,

I'm using the Sherwood PD-4 in my R-4B. Sherwood has a separate installation sheet in a MS Word format just for the R-4B. Rob Sherwood can supply you with that.

Paul,
Tnx for info. So, is it a worthwhile upgrade?
I use my R-4B mainly for CW with a home brew TX and the distortion is distracting.

Bob,

Rob Sherwood has told me the PD-4 it helps with headroom, and since the PD is an active, rather than a passive circuit, it offers better isolation. I can say that my R-4B with all of the mods performed does work and sound very good. You can search the list archives from earlier this year to see what I've done

From: Juan Peiro
Topic: 5913 Message: 5914

The TR4C is not a good option for cw. The shift between the trasnmited and the received signa is 1 KHz, too much for nowadays transceivers designed for a shift of 600 Hz.There are some posible mods, but the risk is to bring the signal out of the FI passband filter. In the paractics, this unusual shift for today produces that your correspondent can´t listen your call or is listening out of his center filter frecuency.The CW model with the RIT allow you to choose the shift you need and is a much better option if you are a cw op.

Mike this is a weighty decision!

The TR-4any does not have 160 meters.

The TR-4CW has a 500Hz cw filter, the TR-4C does not. The TR-4CW/rit is the gem b/c you can tweek a little for better copy what with the slight offset on CW. What you gain with a TR-4 over the TX-4C is the receiver and more output power, (three finals in stead of two).

All that being said, if your really into CW then go for the cw filters 250, 500, and ??? for the R4-C that probably goes with your TX-4C. Much better listening what with Band pass,notch etc.and the TX and R4 will be synchronized. I do have a TR4 CW/rit harnessed with an R4C with the CW filters, but aside from the joy of fiddling with them b/c they are not tied together PTO-wise, there is not an advantage to having the TR-4cw/rit or w/o the rit other than the extra 100 or less watts.

I was thinking of a R4C and use with my TX'r but for simplification I thought just get a transceiver and selll the tx'r. What I think I will do is see what comes available and at what price and take it from there. I'm using a Collins 75S-1 with the TX'r and also use my Eico720 with the Collins as well.

Thanks to all for the responce.

Mike -

If you really want to operate CW, you'd be MUCH better off sticking
with the T-4XC!!

Only the CW and CwRIT have the 500 Hz IF crystal filter.

Mike -

The R-4C would be a much better choice, even over the 75S-1 for CW. CW was an afterthought with the S-1 line, (kinda like the TR-4.)

The T-4XC will transceive with the R-4C, or any other R-4 series receiver, but transceive in general is not suited to CW. EVERYONE likes a slightly different tone, and with the narrow filters some seem to use if a calling station is 100 Hz off your frequency you'll never hear them. Get an R-4C, or even better for CW would be an R-4B.

Mike -

The C IS newer, but is a completely different receiver. I just sent the below on another list to someone who asked the difference between the R-4A and the R-4C..

>>>>>>>>>>

Entirely different receiver. Similar block diagram, but while the 'early' A (yes, there are two distinct versions of the A) is almost 100% vacuum tubes, the C has vacuum tubes ONLY in the primary signal path RF and IF stages, all else is solid state. The A uses L/C filters in four bandwidths, 0.4, 1.2, 2.4 and 4.8 kHz and a noise blanker standard. The C uses 8 pole crystal filters in the second IF, 0.250, 0.500, 1.5, 2.4 and 4 or 6 kHz, each of which is an optional accessory, along with an optional Noise Blanker.

All that aside, the A is a very smooth receiver with excellent audio that you can listen to all day without fatigue, as opposed to the phase distortion and group delay of the crystal filters in the C. For day-to-day hamming, I much prefer the B, which is essentially the late A with a few oscillators converted to solid state. The A _WILL_ transceive with the T-4XC, ALL 4 Series units will 'mix and match' just fine.

<<<<<<<<<<

The 'late' version of the A is similar to the B, primarily cosmetic and minor circuit changes. Aside from the audio differences, the major variance is between the L/C filters in the A and B, and the 8 pole crystal filters in the C. The A/B filters have about a three or four to one shape factor, meaning that the skirts drop off more slowly from the passband, as opposed to the crystal filters that are two to one shape factor with much steeper drop off. The practical result is that with the A/B filters you'll still hear nearby signals, just at a reduced level. The C filters essentially take out everything that is just barely out of the passband. I prefer the 'softer' slope for everyday hamming activity, especially on CW. I like to know what's going on around 'my' frequency! Not insignificant is the difference in cost between the two. The "B" will typically sell in the $200 - 250 range, with the occasional 'bargain' with a rusted chassis and extra holes in the front panel. A "C" will sell for about the same, BUT only the 2.4 kHz filter is standard, each additional filter, IF you can find them, will be between $50 and 125 depending upon bandwidth. If you want (need) a Noise Blanker, it will cost $150 and up, and are difficult to find outside of a receiver.

So that's MY opinion. I have several A, B and C Lines, a 7 Line and a
Collins S-3B-Line. The B Line is on the main desk, the 7-Line is on the
computer desk, and the others are on shelves or in the closet.

Hey Gary,

Lest we forget, R4 A&B are double conversion, while the R4c is a really rotten triple conversion <grin>. After one pays $500 for a box-stock 'C', then pays for the extra bandwidth crystals, then does all the Sherwood mods to get the goodness designed into the radio; to perform like its' potential, you'll have about $1200+ in the receiver. But then it WORKS like a modern contest rig.

Without all that, the R4c is quite mediocre.

I agree with you, the A is good, if you can tolerate the mild drift in it. But the B is a gem hiding behind a low price, buck-teeth, a lousy dress and glasses <grin>. I'll take a B, any day, to backup my TR-4 (if I can find a B in good shape) <wink!>.

To Michael Shelly,

The TR-4c is a great and much improved transceiver, over the TR-4.

But the R4c a is poorly developed triple conversion receiver that never really matched the hype with its' performance. R4a&b came with everything you had to pay extra for in the c model. R4c didn't even come with the NB (which is standard on all other R4's).

If you want a contest grade tube receiver, and you have the pile of money to make it such; get the R4c. But if you want a great receiver with all the bells and whistles, and still performs fairly well at a decent price, get an a or b. Insiders joke I'm afraid <grin>.

Garey,
Just a thought on my part, and a question to you, but what about the TR4C and an R4B (or even the R4A since he can get it for free) as an external receiver using that blasted switch we both hate in it's transceive position?? That would solve the tone problem AND give you some nice CW filtering??? As I started, just a thought I haven't seen voiced.

Don -

I thought those were two different guys, but ...

Not really a 'bad' idea, you just have more invested in the TX part than you need. There really isn't much difference between the TR-4 and the T-4X as far as output power goes. Especially if you follow the 'Revised' tuning instructions for both. The T-4X says I think 340 mA maximum and the TR-4 says 350 mA maximum. Plus you need three PA tubes instead of only two. Even at best, the T-4X will put out 140W on the low bands on CW and the TR-4 only does 200 in perfect tune.

If you HAVE a TR-4(any), then adding an outboard receiver would be a viable approach. But if you have to buy either a T-4X -OR- a TR-4(any) I'd definitely go with the T-4X....

Greetings dear friends

Name is Jhonny call YV5KG from Caracas Venezuela I have one line Drake TR7A, and I have the following problem.

When I go to tranmitir I have no power in my wattmeter RF, the recepsion my radio is very good, but has no 1 watt output is blocked reading several websites for information about pin diode rf stage.

protecting the RF stage but does not generate power using CW and SSB least is the only flaw that presents please if can help me thank all of you will know.

The 12.9 would be 1.5MHz on my R-4A.
I'll take it!

I have two crystals here that are marked spare for DRAKE in my junk drawer.
One is marked 12.90000 T-4XC.
Another marked 9001.5khz ...which rig ??

Free with SASE....otherwise they go to file 13.

5934. RV4C "chirping" in transmit

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-29 16:12:17 UTC
From: billykatzz
Topic: 5934 Message: 5934

My "new" RV4C unit works great in the receive mode, but several ops have reported my CW signal has a chirp when I tried using the unit in the transmit/receive mode.

Looking over the schematic, I see the unit uses a single 12AU7 tube. Could the tube be the culprit, or should I be looking somewhere else?

Bill in Pasadena, NK6Q

5935. TR-7 Blue Filter

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-30 14:35:42 UTC
From: qrpcwop
Topic: 5935 Message: 5935

I dug through the archives, but wasn't able to confirm my belief that the TR-7 uses the same Lee HT-172 Blue Lagoon filter as the 3 & 4 lines.

I installed blue LEDs a couple years ago, thinking that I'll get used to it over time, but it just ain't happening, so I'm going to go back to the ancient incandescent lamps.

5937. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-30 20:35:00 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 5937

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

Thanks, Garey

There's a theatrical supply dealer in town - perhaps I'll get lucky. I've tried the Peacock Blue nail polish route in the past, but had dismal results.

5940. L4B tuning for 10M.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-31 03:00:55 UTC
From: ALAN PHILLIPS
Topic: 5940 Message: 5940

I was using my L4B and my kenwood 940 S during the contest today and I discovered that I can tune up the amp on 10 meters and get a plate I dip in two places. I found this out by accident. The plate control dipped with the pointer on the 15M part of the scale. Grid I was 225, Plate I was around .6 and I had 1 kw out. The audio looked good on the scope.

Then I found the Dip right below the 10M part of the scale and the amp tuned up ok with similiar readings as above. Why would it tune up in two places?

The RF output on my Tek scope looked the same when I talked into the mic on my 940.

Any ideas would be appreciated.

thanks, Al kc9ys

5.22?? Garey..my L-4B manual shows 5.22 as Power Supply...and nothing in the section!

Are there different manuals? Wouldn't surprise me. Mine is the original that came with the amplifier.

5948. Re: [DrakeRadio] L4B tuning for 10M.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-10-31 16:17:39 UTC
From: Garey Barrell
Topic: 5940 Message: 5948

Al -

Section 5.21 5 . 2 1

It describes how to set the knobs on the shafts for the TUNE and LOAD caps. The LOAD points to 9 o'clock with the LOAD cap fully meshed. The PLATE cap should be fullly meshed, the knob attached with the pointer at 9 o'clock. Then tune up on 21.225 MHz, 1000W input, hold the knob and manually push the red pointer to the 15M segment.

And there I thought it was me, Joe. My L4B manual (also original) has NO section markings at all!!! Garey, that manual on WB4HFN's website is difficult for me to follow. Are you meaning he might have the tune and plate knobs misaligned??? I'm confused too.

Don -

Yes. IF the PLATE cap is not 'centered' it's possible to have two resonant points, one on either side of 'end of travel'. When the cap nears minimum capacitance, (10M,) then the end of rotation won't come at precisely 90 degrees or full mesh. So if it's a little 'short' it's possible to tune to say 95% of minimum capacitance at BOTH 95% AND 105% of maximum mesh.

Thank you, kind sir!! When I coorelated the place in the manual with the place in mine, it made good sense. I guess it's like all the 4 line stuff, many different manuals over the years and different schematics. My information does follow the manual on Ron's site, it just was never put into numbered sections. I guess just a different "documenter" at that time.

Garey: So if I tune on either side is it bad for the amp?

I have in my notes that I had 2 dips when using 15 meters on my other L4b. Is this consistent with the cap alignment problem?

Thanks, Al. (in batavia) I wish I had your cell number.

5954. Need specific R-4C Schematic, SN 19K Serial Number

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-01 03:22:47 UTC
From: Jeff
Topic: 5954 Message: 5954

Greetings!

This is my first post to the list, so HI all!

Ok, I caught the Drake bug again after using one back in the mid-70s. I am working on a rehabilitation of an R4C and am looking for a correct schematic. The serial number is in the 19500 range, and it uses 6HS6s instead of the 6EJ7 for three of the tubes. Specifically, I am working on the S-Meter circuit that a PO modified somewhat. My symptom, after replacing the PS capacitors, regulator board and audio output with Sherwood mods, is an S-Meter that is pinned low. The RX is excellent, but the S-Meter circuit obviously needs a bit of help. Does anyone have access to the schematic for this version of the receiver or have a link to one? I can deal with the different tube pinouts, but need a correct schematic if I can find one.

Thanks

Jeff, WI7D

Garey Barrell, who is a very frequent contributor to
this list, publishes several CDs with very extensive
information on Drake equipment. He has stuff there you will
not find elsewhere. I very strongly recommend obtaining them
if you are working on any Drake stuff. His 4C one will have
all the variations on the schematics plus photos. See:
www.k4oah.com They are not expensive.

5959. AC Capacitors

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-03 02:27:16 UTC
From: Don Cunningham
Topic: 5959 Message: 5959

I must admit I must have been asleep, or not needing the info at the time it was presented, but Garey can you expound again on the X and Y capacitor ratings I am seeing on Mouser's catalog and recommend what is good to use for old bypass caps on my Drakes, Collins, Johnson, etc rigs, or point me to a good site?? I see ratings like X400AC Y300AC after many, and am hoping that means they would be good for 110v use. I am putting 3 wire AC cords on all, fuses only on the hot lead, and will save the fused plugs for the purists that don't care about safety and wish to return them to normal.. I want to bypass the lines as I re-wire these rigs.
Thanks,
Don, WB5HAK

5960. Re: [DrakeRadio] AC Capacitors

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-03 03:21:23 UTC
From: Garey Barrell
Topic: 5959 Message: 5960

Don -

Easiest to remember is that "X" capacitors go _across_ the line, and
"Y" capacitors go from either line to ground.

The main difference is that the "X" caps can short when they fail,
blowing a fuse or other protective device. The "Y" caps are designed to
fail 'open' so this cannot happen.

Both are rated by the line voltage they are designed for, but just about
all are adequate for 120 VAC line use. The '1', '2' and '3' ratings are
impulse ratings, or what voltage can be impressed across them for a
SHORT period of time without damage.

There is a good primer at

Thise are the terminal names on the original Switchcraft connector. I'm guessing they mean "ring, tip, and sleeve". Tip is obvious. I suspect that ring is the middle ring, tip is the end tip, and sleeve is the body of the connector. Just my guesses.

Another way to look at it. The mounting nut of the phone jack is ground. One of the wires is the audio input. The other wire, when connected to the ground keys the transmitter. Shorting the mic input to ground won't hurt anything. A LOT of mics do this already when the mic isn't keyed (you have to undo this in the mic to use VOX). Its pretty easy then to figure out which terminal is audio and which is key.

I didn't see a name on your email, so can't do this "personally" but welcome to the group. The RST on your connector stands for Ring, Sleeve and Tip. The Drake manual will show you to hook the shield to the S terminal or the sleeve (the longest metal part) of the connector. Whichever wire is the PTT (push to talk) hooks to the Tip (of course, the very end of the plug) and the audio lead from the microphone element hooks to the Sleeve (the little ring between the ring and the sleeve). You can locate the PTT lead easily by hooking one lead of your ohmmeter to the shield, and see which other wire shows a short only when you push the PTT lever or switch. The other one is the mic audio. Also mic audio is often inside the shield wire if you look closely, and is often white in the old microphones. I don't know the 619 EV mic, but Google it and you will find the wire colors if you can't follow the above.

That said, tell us your knowledge level with tube gear. You can DESTROY the final tubes in our T4XC transmitter if you aren't familiar with tube gear tuning. I don't mean to "talk down" to anyone, but these are TV sweep tubes and are NOT forgiving to abuse.

Again, welcome to the group, and hope you enjoy your C Line. If it needs any TLC, give a look on Garey's website at his CD for the Drake C Line (www.k4oah.com). It's a WEALTH of knowledge for these old rigs.

Another way to look at it. The mounting nut of the phone jack is ground. One of the wires is the audio input. The other wire, when connected to the ground keys the transmitter. Shorting the mic input to ground won't hurt anything. A LOT of mics do this already when the mic isn't keyed (you have to undo this in the mic to use VOX). Its pretty easy then to figure out which terminal is audio and which is key.

73,

Bill

Subject: [DrakeRadio] Microphone Hookup Assistance Please

I just got my license and bought a Drake T4XC/R4C setup. It didn't come with a mic but I did find a Electro Voice 619 Hi Z in my storage bldg. I would like to use it but I don't know how to hook it up. Can anyone help? I found a manual online but I don't understand how to make the connections to my right angle plug. The Plug has three terminals marked R S T. Can anyone help?

If you don't have the instruction books I strongly
suggest getting them before trying to put the transmitter on
the air. One excellent source is the CD offered by list
memeber Garey Barrell. He has not only high rez handbooks
but additional material such as chassis photos which you
will not find elsewhere. www.k4oah.com

HI Ted KI6WIK,

Assuming that everything else is working, you might check the simple stuff.

There is an S-Meter set control on the right-side of the radio. If it is set all the way to an extreme, it can peg the meter minus, to the extent that no signal will be strong enough to make the needle move to the right. Check that with no signal, the meter sets at the left most line on the scale (S-1). Then see what happens with a good signal.

Just a thought.

5975. Drake TR-7 on AM question.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-09 12:18:26 UTC
From: Ed WA4NJY
Topic: 5975 Message: 5975

I am using a TR-7 on AM with good results. I know it transmits carrier and one sideband.

My best transmit audio reports come when mic gain is set for minimal meter upward movement. Same with the scope pattern. If voice peaks approach twice carrier level,
then audio becomes muffled.

Example: Carrier set to 25 watts. Voice peaks at about 40 watts make good audio. Is not that
adding only 15 watts to the sideband? My power supply voltage stays solid.

What am I not understanding here?

Thanks,
Ed Purvis WA4NJY

Ted,
Check two other simple things, the bulb that protects the receiver front end for continuity and it's socket for corrosion. Then the "infamous" RCVR/TCVR switch. I ALWAYS have to check mine after rummaging around behind it to hook up an antenna, etc. One of these days, I'll get around to building the defeats posted everywhere to stop that, but who knows when???
73 and enjoy your TR4 when you get it going,

To Ed WA4NJY,

None of the Drakes have a Mic AGC stage (as far as I've read <grin>). This creates a situation that causes confusion, especially as regards the TR-7s' great SSB transmit quality.

On SSB, the ALC (at the transmitter) limits the sideband output,and therefore maintains good signal quality.

But on AM, the ALC has no usefulness, and most modern SSB radios that have AM, shut the ALC off in that mode. But I suspect the ALC is left on, in AM, in the TR-7, which is actually not a good thing, because the loudest signal in AM is the Carrier. Attenuating the carrier, will tend to create a situation where the modulated sidebands will now get out of balance with the carrier (it's a timing effect), which causes the audio to go into Distortion (the muffled audio you are getting comments on). See the graph below:

```
I
I
I
I I I
I I I
I I I
-----------------
-1 0 1
```

The above is an accurate representation (assuming your email client is running in fixed width font) of a properly calibrated AM signal, with the sidebands. Each sideband is only half the strength of the carrier, when calibrated properly. When either sideband is louder than that, distortion occurs.

Radios that ONLY run AM, put the AGC in the Mic gain stage, so that the audio cannot produce a problem with the carrier. In true carrier AM transmitters, the ALC either is shut off, or does not exist. In low-level modulated radios, the carrier and sidebands are produced in a composite signal generator, then sent to the amplifier.

Most folks that operate a lot of AM in the Ham bands, also operate an oscilloscope to monitor the modulated carrier, and some even have a narrow frame band-scope to see the carrier and sidebands and their relationship; in order to ensure that the signal will not be distorted at the other fellows' receiver <grin>.

In any event, all this discussion is based on the assumption that your TR-7 is running correctly. I hope so. The end of this rather lengthy discussion (I apologize) is that AM mode produces a very complex signal. Ordinary PEP math cannot work correctly on it, unless we use the math to analyze each component separately, and then create a composite answer.

So, to answer your question. Assuming proper operation of your TR-7, AM operators must insure that the carrier output is half the RMS capacity of the radio. And then he must

ensure that there is some kind of Mic AGC (with hard limiting, a standard compressor won't work very well) to limit audio signal from exceeding desired signal quality levels.

Hopefully I've not lost you, and even better if you know this stuff already. Tell me to shut up, if this stuff is not helpful <grin>!

Have fun and good luck!

The TR-4 uses controlled carrier AM. Essentially, the
carrier is nearly 100% modulated all the time but increases
with increasing audio level. This is a type of signal that
can be handled by a linear amplifier which is limited in its
steady-state power handling capability, something which is
typical of linears in SSB equipment. As a result of this
modulation method the readings on a normal power indicator
will be lower than the actual peak power. When you measure
the power you are still measuring both carrier and sideband
but since the carrier power is varying with the audio the
results are not what one would expect from normal AM. The
carrier level is set for no modulation and has no
significance when modulation is applied. Also, there is no
automatic gain control in AM as there is in SSB so audio
levels are rather critical. That also means that the peak to
average ratio in speech is preserved where the AGC or ALC in
an SSB transmitter reduces it resulting in higher average
modulation than one gets with unprocessed speech. The ratio
is pretty high, at least 10db, so _average_ levels of AM

will be quite low.
My guess is that your TX is working normally.

Disregard my last post, I read the model as TR-4 not
TR-7 so my comments may not apply. If the TR-7 does use
controlled carrier AM then the general remarks about
measuring power do apply. I don't know if the TR-7 includes
any compression or other AGC control for AM.

Actually, it is a good thing. The ALC is peak-limiting, as opposed to the compression style (bad) ALC used in a lot of newer rigs. It has little effect on the carrier output, so long as you keep the mic gain within proper operating parameters; i.e., adjust the audio so the ALC LED only flickers occasionally on speech peaks. I think the ratio is something like 3:1 PEP to carrier for proper operation, but I would have to check on that. Note your maximum PEP ouput (which should be about the same as the maximum CW output) and adjust carrier accordingly. Or use a scope, as suggested. Or follow the setup instructions in the manual. An average reading wattmeter will not be of much use under voice conditions, but is OK for measuring CW output.

Thanks to all who wrote via the group and private.
For now, I will be content with the ok signal reports.

Settings will be for minimal meter movement.
 Also the ALC light will flicker very slightly.

The scope has me puzzled. I don't expect to go with the 4:1 ratio of
 a plate modulated rig. Example: 25 watts carrier and 100 watts on peaks.
 Can not put that much power into one sideband.

My scope shows 25 watts carrier and voice peaks at about 40 watts.
 Again, this gives best on air results.

May go with the mod by Jeff Covelli to make it DSB with carrier.

thanks again,
Ed

I don't think conventional ALC would work for AM. Its
way of controlling the RF drive to the final. I think this
can be confusing because in SSB or DSB with carrier
suppression the envelope of the RF follows the envelope of
audio level exactly but this is not the case where a carrier
is present. A conventional ALC would, I think, have an odd
effect on a modulated carrier. Since ALC is trying to keep
the power constant it would see the increase caused by

modulation as an overall increase and reduce the gain thus causing the entire signal including carrier to be reduced as modulation increased. This is not the same as carrier controlled modulation. If the idea is to increase average modulation then the audio signal causing the modulation must be modified to reduced its peak to average ratio. This can be done with a compressor, peak limiter, or peak clipper, all of which would cause a reduction in the ratio in somewhat different ways. Perhaps the best is a combination of a linear compressor and peak limiter, the compressor tending to keep the limiting ratio constant. Some of the devices used to achieve this in broadcasting are very elaborate. The ALC in an SSB transmitter has a similiar effect but does it by keeping the RF drive more or less constant.

FWIW, the constants for conventional AM are:
Peak power at 100% to carrier power = 4:1
Average power at 100% modulation by a sine wave is 1.5X carrier.
Speech waves have a peak to average ratio of at least 10db so overall average modulation with any form of modulation is rather low, perhaps 30%, unless the speech is processed. Average for unprocessed music can be even lower.

The point is, the TR-7 ALC is not "conventional" ALC in the way we have become used to it in the import rigs. It is threshold based and peak limiting, and so does absolutely nothing until you reach a peak level determined by the internal adjustments - generally 140-150 watts on the low bands for a proplerly adjusted TR-7. This is more like th grid-derived ALC of tube rigs than the contunually operating ALC of most transistor rigs. As such, it will have absolutely NO affect on the carrier if you keep the rig out of ALC entirely (ALC LED never flickers), and have a minimal affect if the radio is adjusted properly so that the ALC LED just flickers occasionally on voice peaks. This is where I find a good RF speech processor to be especially useful with the TR-7; whether operating SSB or AM, the clipping operation of the speech processor can be used to keep the radio operating just below the ALC point for the most linear opearation (lowest IMD). ALC action adds IMD, and the ALC action of many more recent rigs is the worst. See http://www.sm5bsz.com/dynrange/alc.htm

You can't think in the same terms with the TR-7 as with most other solid-state rigs. With other rigs, it's OK to have some considerable ALC action (on SSB) as long as you stay within the marks on the meter. As you described, this is not an ideal system for AM. With the TR-7, if that LED lights up, you are at your peak. Lighting it up more is bad. Not lighting it is no ALC action at all. The design of the system contributes to the stelllar audio reports that a well-kept TR-7 can solicit. So, for best AM, the ideal point would be to operate just below the ALC threshold. But an occasional flicker is probably OK.

Keep in mind that Jeff's (excellently concieved and written) mod does miss one important point: proper centering of the carrier in the AM filter. I wrote up an easy fix for this somewhere, probably in the Drakelist online forum, but I think it's largely been ingnored.

Thinking back on this comment, I think this is where some confusion is happening. If you look at the signal in the frequency domain, yes. WIth a conventional AM signal, the carrier has the highest amplitude. But ALC works in the time domain. You can think of it as being like the envelope detector in a peak reading wattmeter, or the image on an oscilloscope. The ALC works on the peak of the envelope, or PEP power, which is always higher than the unmodulated carrier (unless you are horribly overdriving the PA). Regardless of the number of sidebands.

To Jim Shorney NU0C,

I'm not confused about this. The statement I made is correct. Even if we use your comment, nothing changes the end results. The end results of ALC on a AM signal is that because of the indirect effect in the time domain (the direct effect is the result of ALC sense doing a reaction, the timing is not planned, but is a result of the ALC's action), the carrier will be effected at a different point, than the sidebands, and can easily cause distortion of the audio in a receiver. This is often caused by the ALC having a timing constant that exceeds the timing duration by frequency of the entire signal envelope containing a sideband, a carrier, and another sideband. The carrier can be effected while the ALC completely skips over the sidebands, because of their smaller amplitude vs the much large amplitude of the carrier against the timing constant involved.

In some ways, this is the same timing effect that we see with a AM signal coming in from Skip, The phasing and distortion is caused by the carrier and sidebands being effected by the ionosphere at different timing constants, both because of the instantaneous effects of atmospheric waving, but also because of the effect of the Sidebands and Carrier hitting the ionosphere at literally different frequencies in time.

The arithmetic we are given by manufacturers (that is carrier should be 25% of PEP) is a bunch of baloney. If you look at the output of an AM signal in the time domain, you see a properly generated signal producing a carrier which contains 50% of all power emitted (not voltage). That means that a carrier AM signal with modulated peaks at 150-watts should contain a carrier at 75-watts. If the transmitter cannot produce a good signal with this arithmetic, then there is design problem in the transmitter or the power supply is not rated for at least 50% duty cycle over multiple sinewaves.
If we look at an audio oscilloscope trace of the same signal (assuming sufficient power supply) and we take for granted a properly modulated signal; if we drop the carrier, we don't get distortion, because the power supply is sufficient to produce a clean sinewave, but the result will be harmonics all over the RF domain; if we leave the carrier where it needs to be for PEP, and then increase the audio drive, we will flat-top the audio, this cause both harmonics AND audio distortion because now we ARE exceeding the power supply <grin>.

This isn't rocket science, it's just simple arithmetic. But it still means that if good voice quality is a concern, that a good voice limiter AGC is required, to maintain good saturation without exceeding the sideband relationship against the carrier.

Drake transceivers are mainly a SSB transceiver, and the AM-mode transmission facilities are pretty obviously not as well thought out. A TR-7 is a great radio, and hears quite well in all modes, but this does not necessarily translate to a all-mode transmitter as well.

Great comments Jim, it allows us both to vent some frustrations that we've been having over the years <grin>.

The bulb will not light up, but should have continuity through it. You may be able to access the socket from the under side of the chassis for an ohmeter check. I think, and it's been a LONG time since I've been in a TR4, mine is the TR4C, that the whole PA cage will have to come off to get to it. Some of the series has the bulb under the chassis, which is MUCH easier.

The end results of ALC on a AM signal is that because of the indirect effect in the time domain (the direct effect is the result of ALC sense doing a reaction, the timing is not planned, but is a result of the ALC's action), the carrier will be effected at a different point, than the sidebands, and can easily cause distortion of the audio in a receiver. This is often caused by the ALC having a timing constant that exceeds the timing duration by frequency of the entire signal envelope containing a sideband, a carrier, and another sideband. The carrier can be effected while the ALC completely skips over the sidebands, because of their smaller amplitude vs the much large amplitude of the carrier against the timing constant involved.

True, because the ALC in the TR-7 is a simple AM detector that responds to the envelope of the signal. When the peak of the envelope exceeds the preset threshold, the ALC circuit generates a control voltage that operates a PIN diode attenueator in the transmit RF path. Until this happens, the transmitter is operating entirely linear. The pin diode attenuator reduces the gain of the circuit in order to keep the peak output within the established limit. This has the effect of reducing the carrier, because it is at a lower level than the maximum PEP output. It was my belief that a properly adjsuted TR-7, with the ALC light just flickering occasionally on voice peaks, will have a *MINIMAL* affect on the carrier. A golden ear with a good receiver might hear the occasional distortion products. Keep the radio out of ALC entirely, and there will be no effect.

>The arithmetic we are given by manufacturers (that is carrier should be 25% of PEP) is a bunch of baloney. If you look at the output of an AM signal in the time domain, you see a properly generated signal producing a carrier which contains 50% of all power emitted (not voltage). That means that a carrier AM signal with modulated peaks at 150-watts should contain a carrier at 75-watts. If the transmitter cannot produce a good signal with this arithmetic, then there is design problem in the transmitter or the power supply is not rated for at least 50% duty cycle over multiple sinewaves.

Again, true if you look at it a certian way. But you can't change the math. If the peak voltage of the envelope at 100% modulation (PEP) is twice the voltage of the carrier, the total power in the composite waveform is greater by a factor of 4. A 100 Watt PEP AM signal will have 25 watts of carrier. Or to look at it another way, that's why SSB CB rigs can operate at 4 Watts AM carrier, or 16 Watts PEP SSB - it's the same power level! You can work out the math, E^2/R doesn't lie. At least, that's the way it works with any scope pictures/diagrams I've ever seen.

> If we look at an audio oscilloscope trace of the same signal (assuming sufficient power supply) and we take for granted a properly modulated signal; if we drop the carrier, we don't get distortion, because the power supply is sufficient to produce a clean sinewave,

but the result will be harmonics all over the RF domain; if we leave the carrier where it needs to be for PEP, and then increase the audio drive, we will flat-top the audio, this cause both harmonics AND audio distortion because now we ARE exceeding the power supply <grin>.

True. That's IMD. THe web page I referred to previously demonstrates how improperly implemented ALC causes increased IMD in SSB transmitters.

>Drake transceivers are mainly a SSB transceiver, and the AM-mode transmission facilities are pretty obviously not as well thought out. A TR-7 is a great radio, and hears quite well in all modes, but this does not necessarily translate to a all-mode transmitter as well.

I think the TR-7 did it better than a lot of other solid-state radios. For one, they didn't try to generate the carrier by unbalancing the balanced modulator.

>Great comments Jim, it allows us both to vent some frustrations that we've been having over the years <grin>.

Likewise. :)

HI all, Well late last night I decided to put my r4/t4 back on the air after about 6 months. Well Hooked everything up wired up a new Sure444d and turned on the power to the r4 and the t4 and went about finding the right antenna swtiching(too many radio's etc) well as I was swtiching listening for a noise increase. and ....

Bang bang bang and the blue smoke started comming out of one of the paper caps in the ac3. Well other than this not so news worthy event. The reason for my post...

Does anyone have the inclination to to do a Heathkit shop upgrade on this PS for me?

Yes I agree I should be able to do this myself but atm time and other projects are those in demand.

I am willing to pick up the premade pc board and if someone wants to either walk me through it or have a go at it. I'll be glad to hand deliver in New England or ship if necessary

thanks in advance

de John ko1h

The bulb in the TR-3/TR-4 series transceivers is not a fuse. It is a 'negative temperature coefficient resistor', which is a fancy name for a resistor that goes UP in value when heated by
current through it.

Remember that these units were designed for mobile use. This means you could pull up next to an 18
wheeler with a kw on CB with his antenna six feet from yours! Or even another ham running a few
hundred watts. This much power can severely damage input coils, etc., if not current limited.

Obviously Field Day is another situation where the bulb might be important, with other transmitters
very nearby.

Since the 'normal' current through the bulb lead / socket interface is so tiny, it doesn't take much
corrosion to severely limit the signal strength to the receiver. This bulb is the 'second' most
common culprit in 'I hear signals, but the S-Meter barely moves' cases. The TR- receivers have over
100 dB of gain, so a very small signal (0.5 microvolt) can be 'heard', but it's not gonna move the
meter!!

5999. TR7 Troubles

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-11 19:38:52 UTC
From: Paul Horvitz
Topic: 5999 Message: 5999

Hello all,
Any ideas or suggestions would be welcome with this:

---With the translator board plugged in,
pin 11 on regulator chassis pins reads grounded (+5vdc regulated)
pin 10 on regulator chassis pins reads grounded (+10vdc regulated)

Q2101 (2n5986) for the 10vdc out on regulator board gets very hot in a couple seconds...way too hot. Can smell it's hot, also with finger on it is too hot to touch in 5 seconds.

---With translator board out of the rig,
pin 11 on regulator chassis pins reads 180k to ground
pin 10 on regulator chassis pins reads 80 ohms to ground (reading swings as electrolytic to gnd. settles down till the reading reaches and stays at 80 ohms)

Q2101 is nice and cool, 5v reg OK, 10v reg OK...measured them.

The 5v reg and 10v reg go from pins 13 (5v) and 14 (10v) on translator board, through motherboard to those pins 11 and 10 on regulator but when I measure resistance to ground on them at the translator board socket header I get readings of 3.1k on pin 13 (the 5v) and 5.1k on pin 14 (the 10v). Not shorted to ground.

I've traced this out three times, two different days each so am fairly certain I've got a lock on the 5v reg and 10v reg flow/connections.

How come those pins on regulator board go to ground potential with translator plugged in yet not shorted to ground on translator its self? Doesn't make any sense to me.

I've tested all parts except for the 4 I.C.'s on translator, started with those notorious tantalum caps, but all is OK. Note that the 4 MBD101's were tested in circuit but I got .202 volts dropped across their junctions, except for where that toroidal coil is across 2 sides so they seem OK.

Where am I going wrong or not thinking straight with this?
Am thinking about buying another translator to try substitution.

Tnx,
Paul

Paul -

We have others on here who are more familiar with the 7 than I am, but it looks to me like the short
is on the +10V Reg line. A ground on this line would also kill the +5 Reg. +10 V Reg goes to the
Collectors of Q603 and Q604, so that is the suspicious area. Possibly a shorted transistor, possibly C620, C621, C635, or ...

When checking resistance, don't forget to reverse the ohmmeter leads just in case there is a diode
junction somewhere!

From: Paul Pollock
Topic: 5975 Message: 6001

Hi Jim NU0C,

Instead of making a hodgepodge, I'll try to address all of your comments in one go <grin>.

1). First, "keep the radio out of ALC entirely, and there will be no effect".
Quite right, but then there is no way on Earth of knowing your modulation percentage, or whether your splattering in harmonic energy. But the audio will be fairly listenable.

But, we are overlooking that normally the ALC begins its attack at a point significantly earlier than 100% PEP, in most solid state transmitters (makers don't like blown transmitters, and like to under-rate the devices by being conservative with their ALC). So where does that leave us if we DON'T crowd the ALC a bit?

Keep in mind, there is a FCC mandate for all transmitters (including HAM), that average modulation should be maintained at more than 50% in modern equipment (that's a laugh, the rule was written when tubes were still the norm <grin>). Because of this mandate, manufacturers started thinking a lot about compressors and mike AGC with hard limiting (I can't think of a single solid state CB radio that does-not have a mic AGC/compressor superior to just about anything in HAM radio for 6 times the price). Even Drake built the SP-75 to assist the TR-7 in this regard (anybody have $800 for an SP-75? Geez people have some interesting ideas on what stuff on EBay is worth).

2). "Again, true if you look at it a certain way. But you can't change the math."
Yea, actually I can. There is no way to ascertain the PEP envelope of an AM signal without breaking out each component of the signal, then summing the results. This is because a changing signal in the sidebands can be plugged into the formula normally (but separately), and the carrier output must be viewed as a PEP and the RMS simultaneously. This means that all the math is wrong because of bad assumptions in the real world.

Let me give an example in the real world. Don Dumont was a friend of my father. He was the chief engineer of KFI-Los Angeles, and help install the original C-Class plate transmitter (50KW) (they changed to a modern transmitter about 15-years ago). It consisted of a 25KW Carrier generator, and a 25KW audio modulator. No special math, no figuring what's going on here. It made 50KW, of clean AM signal. He pointed out to me, as a teen, that 50% of all power produced was in the carrier. To hell with the formulas, they are just plain wrong.

When I studied the math for myself, the relationship of PEP to RMS was .707 or 1.414 (depending on which conversion you were using), except for an exception that even the books of the times laid out. And that was that a continuous carrier PEP was equal to the RMS of that signal. The only reason PEP was invented is because engineers of the times needed to be able to plug numbers into formulas that equated a dynamically changing signal (the modulated waveforms). Before voice communications, PEP math didn't even exist. This changes the formulas modern math geeks use to something that needs to be assessed differently. Modulated AM signals cannot be plugged into the formula without changing the modern assumptions.

In other words, screw the math, it's a bald faced lie, and 50% of the PEP of a transmitter is in the carrier. There is NO exceptions to these assumptions. Throw out the math, and look at the signal waveforms; they don't represent voltage, they represent power.

This argument holds quite well, even if we look at the average CB radio. A properly built SSB CB radio can produce 6-watts fully modulated AM Carrier without distortion or IMD, while still producing 12-watts of PEP SSB. Actually, many of them can make more than 20-watts PEP, and the only reason they won't modulate AM past about 11-PEP is because the power supply needs beefing up and a stronger driver needs to be used (manufacturers hobbled the radios. Remember, the FCC type certifies all CB radios. If they are built to HAM standards as regards the transmitter, they get rejected). I've aligned many SSB CB radios in my time, and that is the true arithmetic. The rules are made by the FCC, to continue a fomented lie, written 50-years ago.

This conversation even extends to people wanted to go legal-limit for Modulated carrier AM. The carrier number is not 375-watts. It's 750-watts.

Look, you can even prove this out on a power supply power metering system (you can even check on a power oscilloscope if you wish). A properly calibrated power gage will read approximately half, on a modern radio, of what it should; because the assumptions designed into the radio for carrier-AM are wrong. If the same radio can make 100-watts in FM, and consume 300-watts to make it, how come the same radio is consuming less than 200 watts on a fully modulated AM signal? If we inject a 1-Khz tone at the mike jack, and modulate fully, a properly designed 100-watt output radio should produce 100-watts PEP, and it doesn't. The assumptions are wrong, which causes the math to be erroneous.

There are no side issues here, no man behind the curtain, no extra math assumptions to deter the basic conclussion. In short, there is nowhere for the FCC (for example) to run. They are either lying or they are ignorant; no third choice. And they used this lie (or ineptitude) to write a rule, that gets enforced as a Federal Law.

3). "I think the TR-7 did it better than a lot of other solid-state radios. For one, they didn't try to generate the carrier by unbalancing the balanced modulator."

Unbalancing the balanced modulator is a technique used in the TR-4 (at least that's what my manual says). Unbalancing a modulator is a lousy way to do things, but only if we are NOT restricting the conversation to why the makers did that. It was done very early on (as Drake did), to create a sideband radio that could pass as a AM radio with one(1) sideband. It is a very simple means of doing a "me too" <grin>.
However, the TR-4 generates a carrier-AM signal with one advantage over modern gear. TR-4 uses controlled carrier, to produce AM. This means that everything responds as a modulated wave, and has a stronger sound than low-level modulated AM. This also means that an amplifier designed only for SSB service will not overheat producing a continuous carrier as happens with SSB amps (virtually everything available today) driven by a modern continuous steady carrier AM signal. Carrier transmitting devices need to be built much more ruggedly, because there is no instantaneous moment relaxation available for cooling (which modern SSB amplifiers rely on). Unless... they are driven by a controlled carrier transmitter (SSB can be lumped into that label).

Very few solid state radios used unbalancing to produce AM. Almost all of them, produce real Carrier-double-sideband AM. In all newer radios, the composite signal is made in a composite signal mixer-generator, and then piped to the transmitter stage (we call this low-level modulated). Really, really new ones produce AM, SSB, FM, in the DSP <grin>.

Modern equipment bypasses the balanced modulator altogether. This means that all modern equipment, from about the mid-80's or so, did different transmitting modes, with different methods for each mode (just as they do for receiving).

Again, this was fun; thanks for the time Jim.

Paul

It may help to open up the supply lines on the translator board to narrow down the problem. Try lifting one leg of RFC 601, 602, and 603, one at a time, to see if the problem goes away.

Another thought is the possibility of conductive debris beneath the header on the main board, which causes a short when the translator board is pressed into place.

Yes, that same thing happened to me too. The AC3 bias voltage went crazy because of an old paper cap went south. Which also sent the finals to meltdown because of the absent bias voltage. The Heathkit shop board/fix is great. It's easily worth it. Good luck and check those finals. Oh, also look at the resistors underneath the finals.

the lamp is a fuse . not sure what it is supposed to protect against . I have seen the one in the my TR3 light up the time I took it to field day . the TR3 would not receive when I got it . had to remove the lamp and clean it's pins and socket .

good luck with it . when you get all the bugs out you will enjoy it .

If it is set all the way to an extreme, it can peg the meter minus, to the extent that no signal will be strong enough to make the needle move to the right. Check that with no signal, the meter sets at the left most line on the scale (S-1). Then see what happens with a good signal.

John,
Contact Mike at the Heathkit Shop, he will do the rebuild for you. He charges, as he must to make a go of it, but will do a great job and you will be in business. However, he can't follow it home to make sure it didn't do some damage in the process, as others have reported!!!!

Ted,
Just remember, as Garey said, only a miniscule amount of corrosion on the pins of the #12 lamp or the socket WILL attenuate the receive signal greatly. Same on the receive contacts of the T/R relay. Careful use of DeOxit will cure a lot of ills in those areas.

Visually inspect the placement of the components on the translator board near the Molex connectors. I've it happen that a component will be bent too closely to a connector, and the male pin from the parent board will pass through the female connector far enough to short to the component when plugged in.

I think that's postive temperature coefficient. Resistance increases as temperature increases. NTCs are whats in power supplies to limit inrush; resistance goes down as temperature goes up. Using a lamp as a protector is not unheard of, Bose had some problems with chronic tweeter destruction in the 301 bookshelf speakers in their early life. Not really a design fault of the speakers so much as people powering them from underpowered amps driven to clipping, causing the tweeters to burn out from too much harmonic energy. The "fix" was an automotive dome lamp bulb and socket sent out with each replacement tweeter, to be wired in series with the tweeter. It worked, we never saw one come back.

Then there's the "dim bulb" tester, a light bulb in series with an AC line cord, that comes in handy for bringing up old equipment under controlled conditions.

Ted,
I really didn't mean to replace the bulb, just clean the pins and the socket pins as well. Just a drop of DeOxit goes a LONG way, so don't overdo it. No sense changing a good bulb, they are getting hard to find. Also, just soak a side of a business card (or similar thickness cardboard) with DeOxit and drag it between the contacts. Nothing fancy, just will improve even a "shiny new" looking one.

Ted,
I'm trying to do too many things at once, as usual. The "business card" trick was for the T/R relay, NOT the #12 lamp, of course. If it's a sealed relay and is actually a new stock one, maybe not necessary. Some companies will say to run a small current through the receive contacts (on the bench, out of the rig, of course) to "clean" the contacts, but I've not done that. Even on the gold contacts on the crypto gear in Vietnam era Navy ship radio rooms, we used a new, crisp, 20 dollar bill to scrub the contacts. Not sure this new "play money" has the same abrasives as the good, old real stuff, hi.

Hi Paul,

On Fri, 11 Nov 2011 15:26:16 -0700, Paul Pollock wrote:

>But, we are overlooking that normally the ALC begins its attack at a point significantly earlier than 100% PEP, in most solid state transmitters (makers don't like blown transmitters, and like to under-rate the devices by being conservative with their ALC).

Actually, that's the point that I brought up in the early part of this discussion about how the TR-7 ALC is different than most other "modern" rigs, and is also addressed on the "Abominable ALC" page by SM5BSZ that I pointed to.

>Keep in mind, there is a FCC mandate for all transmitters (including HAM), that average modulation should be maintained at more than 50% in modern equipment

I must have missed that one, because I've never heard of it, at least WRT ham transmitters. I'd like to see a citation on that.

> (I can't think of a single solid state CB radio that does-not have a mic AGC/compressor superior to just about anything in HAM radio for 6 times the price).

I can, but that's another discussion. It was always my impression that the FCC mandated modulation limiters in CB radios to mitigate the tendency of CBers to buy power mics and crank the audio up to "get out better". It's been my experience that mod limiters in a lot of the CB rigs are downright junk, barely doing what they are supposed to do at best.

>Even Drake built the SP-75 to assist the TR-7 in this regard (anybody have $800 for an SP-75? Geez people have some interesting ideas on what stuff on EBay is worth).

Funny, I keep mentioning that I have one of those. :) There are other RF speech processors out there that do good jobs, various models by Daiwa an Ten-Tec, even the old Comdel(?) that turns up at hamfests cheap because people don't know what they are. for example. MFJ has even made RF processors, although I don't know that I would trust one. I wouldn't pay over $150 for an SP-75 if you have to have that model, and I think that is even a little high.

>2). "Again, true if you look at it a certain way. But you can't change the math."
>Yea, actually I can. There is no way to ascertain the PEP envelope of an AM signal without breaking out each component of the signal, then summing the results.

I don't mean to be flip, but then please explain to me how E^2/R is not valid. Maybe it's a difference in parameters, I've been referring to the composite waveform that does the work in the real world. Or is it some sort of qauntum thing?

http://xkcd.com/967/

Ok, seriously. Is the relationship not what it seems? Back up a little, I've had the argument before on how to define PEP, it's not really relevant. Use whatever you want, peak, RMS, the numbers work out the same. I'll use RMS of one cycle of RF at the point of interest of the composite waveform, as seen on a scope or from a simple AM envelope detector. So, let's present a carrier of 1 volt RMS across a 1 Ohm resistive load. Pretty simple, E^/R gives us one Watt. Now add a 100% modulated sine wave. The peak of the waveform is 2 Volts RMS over one cycle of RF at the peak. E^/R gives us 4 Watts. Plug in any number you want for the carrier, it works out to 4 times the power at peak/PEP/RMS/whatever.

Why is this invalid? Is the relationship not linear? i.e., is the peak voltage at 100% not twice the unmodulated carrier? Wouldn't this prevent us from ever getting undistorted audio from an AM detector if they work as the textbooks tell us? What am I missing?

>This is because a changing signal in the sidebands can be plugged into the formula normally (but separately), and the carrier output must be viewed as a PEP and the RMS simultaneously. This means that all the math is wrong because of bad assumptions in the real world.

Ummm, yeah. I don't follow that. How does a scope or a diode detector know this? All it knows is an RF waveform that is varying in amplitude at an audio rate. The fact that sidebands and varying phase/amplitude relationships are there makes no difference, they are all mashed together into a resultant waveform that looks and acts like an RF sine wave varying in amplitude at an audio rate in the real world. I'll admit that a diode detector is a nonlinear device, but my scope shoud be pretty linear. Sure, we can look at PEP an RMS simultaneously, but don't we only use one at a time when doing measurements or calculations?

FWIW, PEP is defined in Federal Standard 1037C as:

"peak envelope power (of a radio transmitter) [PEP, pX, PX]: The average power supplied to the antenna transmission line by a transmitter during one radio frequency cycle at the crest of the modulation envelope taken under normal operating conditions."

http://www.its.bldrdoc.gov/fs-1037/fs-1037c.htm

Sounds reasonable to me.

>He pointed out to me, as a teen, that 50% of all power produced was in the carrier. To hell with the formulas, they are just plain wrong.

Ok, let's just throw out Ohm's Law and the power formula then.

>When I studied the math for myself, the relationship of PEP to RMS was .707 or 1.414 (depending on which conversion you were using), except for an exception that even the books of the times laid out.

OK, wait. PEAK is 1.414 of RMS, or RMS is .707 of PEAK. Peak Envelope Power is a different animal. Peak is the maximum value at the crest of the waveform. PEP (Peak Envelope Power) is defined (as above) as the AVERAGE power of a single

cycle of RF at the crest of the modulation envelope. In this case, average power is defined as E(RMS)^2/R, so you could also say that PEP is the "RMS power" of a singly cylce. Peak power would be E(peak)^R. That nasty square root of 2 sneaks in there again. We really should ban it. Call the EPA!

> And that was that a continuous carrier PEP was equal to the RMS of that signal.

That's not a special case, that's just the way it is. In this case, The average power of any single cycle of a continuous carrier is the same as the average power of any other single cycle. No magic there. The assumption there is that average power = "RMS power". Is that where our numbers are at odds?

>In other words, screw the math, it's a bald faced lie, and 50% of the PEP of a transmitter is in the carrier. There is NO exceptions to these assumptions. Throw out the math, and look at the signal waveforms; they don't represent voltage, they represent power.

But it all has to match up, you can't get something for nothing. Otherwise, I need to stock up on magic wands, fairy dust (and magic server pixie dust if IBM still has any), and Harry Potter glasses. You can't say "screw the math" without some heavy artillery to back that up!

> If we inject a 1-Khz tone at the mike jack, and modulate fully, a properly designed 100-watt output radio should produce 100-watts PEP, and it doesn't. The assumptions are wrong, which causes the math to be erroneous.

I'm still not seeing precisely where the incorrect assumption(s) are. I should be able to empirically test this, right? Assume that I have a radio with a linear RF chain, and keep it out of ALC. I put a 1 KHz tone into the mic and adjust the audio level for 50 watts RF out on SSB. This should effectively be a 50 Watt PEP signal, very closely emulating a continuous carrier. My wattmeter tells me so, and E^2/R tells me so. I'll then insert a 25 watt carrier and re-apply the same tone at the same level, without altering the audio gain settings. I should see 100% modulation on the scope, no? I can do this, since my TR-7 is modified for DSB AM and any minimal carrier leakage with the carrier control set to zero should be insignifigant. Now, I would expect that things would change when two sidebands with no carrier are involved as opposed to one, but from 2:1 to 4:1? 3:1? This should be an interesting test. I would need to remove the bottom cover and disconnect a couple of wires to return to SSB AM, but it might be worth the trouble to see what happens. If nothing else, it would answer the question of how things are different between SSB with carrier and DSB with carrier WRT power readings, gain settings, etc. If I see what you expect me to see, that would imply that other assumptions about the way our electronics work are faulty as well. Where there's smoke, there's fire.

If the parameters of my test setup aren't valid, I'm sure you will tell me. :)

>Very few solid state radios used unbalancing to produce AM. Almost all of them, produce real Carrier-double-sideband AM.

Hmm, I'd have to check that, but I probably don't have the time to wade through a bunch of manuals to figure out how they do AM. The TR-7 produces AM at the tail end of the chain, and is not controlled carrier as in the tube rigs; the

balanced modulator and IF chain function as in SSB, with the carrier oscillator signal re-inserted in a summing amplifier on the 2nd IF/Audio board (just before the spot where ALC is applied, as it happens). Probably not the best way to do it if you want to maintain proper phase relationships, because you're passing the supressed carrier signal through several stages and the crystal filter before you get the carrier back, but it works well enough and sounds fine to most people. Jeff's mod for DSB simply switches in the AM filter for transmit, instead of using the default SSB filter. I had actually thought about trying that some time ago, but Jeff beat me to it. He did miss the fact that an extra step needs to be taken to center the carrier in the AM filter bandpass, but it still works.

>Again, this was fun; thanks for the time Jim.

Yeah, fun. Let's take down math! ;)

I believe that dark is a component of the magic smoke that makes our electronics work. If you have ever noticed, the darker the smoke that exits, the greater the damage to your radio. Too much dark has escaped in the smoke for your radio to function. This is clearly evident when the dark sinks in your radio have removed a lot of dark from the air in a short period of time via lightnig. The quantity of dark involved in lightning is so everwhelming that much of it escapes with the magic smoke that is released, and often residual dark trapped in solid form is left in the areas that used to have components.

Dark is also a component of AM, to keep this on topic. If you look at the screen on your scope when there is no waveform, is is mostly covered by a low level form of dark. The sinewaves that we see on our scope are actually blocking the dark, and this is how we are able to detect them. If you look carefully at the spaces between the sine waves and under the modulation envelope, they are dark. Ths is where that extra power is coming from, there is a quantum reaction between the dark and the dark-blocking sine waves. I think it's something akin to zero-point energy, perhaps zero-dark energy?

Long thread snipped...

An automatic load control is essentially a compressor working at RF to prevent the final amplfier from being driven into an nonlinear condition. ALC is used in linear RF amplfiers for use on carrier suppressed amplitude modulated signals. A linear amplfier can also be used to amplify a full carrier AM signal, most early broadcast transmitters were low-level modulated using linear amplfiers to gain the final output power.
For a carrier suppressed signal the output _can_ vary from zero to some peak maximum. The amplfier has a definite limit on how much power it can deliver to the load within some distortion specification. The idea is to keep the drive from exceeding this output.
Amplitude modulated signals have a constant carrier level which is present whether or not its modulated. The peak during 100% modulation is four times the constant, unmodulated power, or twice its voltage. If a linear amplifier is used for AM it must be capable of undistorted ouput at this peak level.
Now, lets consider what an ALC or AGC circuit is actually doing: The assumption in using one is that the input signal is varying in some fashion that requires controlling. The control can be applied in two places: 1, the input signal itself before modulation; 2, the signal after modulation, that is, the drive signal to the final amplfier. The usual ALC is arranged so that it senses some condition in the final amplfier, say grid current, that indicates overdriving and generates a control voltage to be applied at some earlier stage such that the drive is reduced. This type of ALC should have little or no effect below some threshold. It is essentially a peak compressor.
In conventional amplitude modulation (because SSB is also amplitude modulation) the carrier is always present and is of a constant value. The modulation does not vary it but rather adds an additional signal in the form of sidebands.

When such a signal is amplfied by a linear amplfier the amplifier must have a sufficient linear range to accomodate the peak power value at 100% modulation, i.e., four times carrier power or double carrier voltage. If an ALC system such as used for SSB is applied here it must be so adjusted that the threshold is at the 100% modulation peak level.
Now, what happens if we use this sytem? It controls the _overall_ drive, that is both carrier and sidebands, into the amplfier so that if the sideband energy is increased both sidebands and carrier will be reduced in level. Now, if the AM signal being amplfied is overmodulated the ALC does nothing about this, it simply keeps the overmodulated signal in the linear range of the amplfier. One of the effects of overmodulation is to cut off the carrier on negative peaks thus causing RF distortion and "splattering". This effect is not affected by the ALC because it has no control over the _modulating_ signal, only the _modulated drive signal_. As a result it will not eliminate problems caused by overmodulation. Please note here the difference between distortion causing RF interferrence from an overdriven linear amplifier and distortion which is a part of the _modulating_ signal and is being amplified quite linearly by the amplifier. The sources of the distortion are quite different.
If one wants to eliminate distortion due to overmodulation of an AM signal it is the _modulating_ signal which must be controlled so that it never exceeds the limits for 100% modulation. That is commonly done using an AGC amplfier _ahead_ of the transmitter or which may be a compenent in the audio system of the transmitter. Such audio level control is sometimes done by converting the audio signal to RF and processing at an RF frequency, but that is completely different from attempting to process it in the RF stages of the transmitter.
Time constants: All gain control circuits have time constants, that is, they do not respond linearly to the amplitude envelope of the signal they are controlling. For audio the time constants used for attack and release time depend on the nature of the signal they are processing, i.e., the optimum ones (if such exist) are somewhat different for music, high quality speech, and communications speech. In the ALC another set of requirements exist because even instantaneous overload of the amplfier will produce distortion that results in RF interference so that the ALC should ideally have instantaneous action.
Now, in practice, ALC circuits in SSB transmitters are often used to accomplish the same results as processing of the modulating signal. They can not do this properly because the requirements for the time constants are, in general different. Nonetheless, a decent ALC will allow some

increase in average vs: peak power in speech. Ideally, the
ALC should never have to do anything and modification of
speech or other varying modulating singnal should be done
previous to modulation. This is sometimes done and some
transmitters include audio AGC circuits or clippers.
For speech the typical ratio of peak to average is
around 10db so that the judicial application of some
compression, peak limiting, clipping, or some combination,
can result in a substantial increase in the average level.
This is important where the transmission system is strictly
amplitude limited, as it is for all forms of amplitude
modulation. By applying some compression and some frequency
domain filtering to the speech signal its effectivness in
overcoming noise at the receiving end can be substantially
increased, which is what is desired.
For conventional amplitude modulation the application
of pre-modulation processing can also result in a
substantially inreased average modulation level which also
results in a "louder" signal at the receiver. All amplitude
or frequency processing is "distortion" in that the signal
following it is different in some way from the original, but
sometimes this "distortion" is benificial. It can be
overdone as a survey of local broadcast stations, especially
in large markets, will rapidly demonstrate.
The math for all types of modulation may be found in
many text books, written with varying clarity, it probably
helps to look at more than one source. Also, the application
of peak envelope power by the FCC in its regulations is, to
say the least, confusing. For instance, their maximum power
regulations for SSB and CW make some sense, the
specification for AM does not.
A final note: somewhere in this thread someone stated
that the FCC required broadcast stations to maintain at
least 50% modulation at all times! This is, of course, am
impossiblity. I think what is meant is that transmitters are
required to have a modulation _capability_ of at least 50%.
This is a very old regulation and I don't know if its still
in effect. It was meant to eliminate some very early
low-level modulated transmitters (modulated oscillators for
instance) which had very severly limited modulation
capability (maybe 30% maximum). It would certainly not apply
to any commercial transmitter built in the last about eighty
years.

Yes. Exactly the way the ALC in the TR-7 works. Well, except for the grid current part. A sample of the output of the forward power sensor, a simple AM detector, is applied to a comparator. When the preset threshold is exceeded, ALC control voltage is generated. The threshold is typically set at the level of 140-150 Watts forward power, into a 50 Ohm resistive load. The ALC board also incorporates the SWR shutdown protection, with a sample from the reflected power sensor applied to another comparator that causes the ALC to activate when VSWR is too high.

My SP-75, which will never leave my hands. It is an RF processor (compressor/clipper) that functions at the mic audio point. It does a very good

job leveling the peak output when adjusted for 6 to 9 dB of clipping. I will typically run the radio just below the point where the ALC activates, and it seems to work very well. I will admit that I have made exactly one contact on AM within the past few years on the TR-7, so this is an area that I need to play in more. :)

> Now, in practice, ALC circuits in SSB transmitters are

This is what SM5BSZ addressed on his "Abominable ALC" page. Very interesting reading, and this article is what led me to avoid running the TR-7 into the ALC point as a general rule. Not to say that it is a major problem in the TR-7, I don't believe that Drake intended the ALC to operate as syllabic compression as described in the article, I just like the idea of a cleaner transmit signal.

> Nonetheless, a decent ALC will allow some
>increase in average vs: peak power in speech. Ideally, the
>ALC should never have to do anything and modification of
>speech or other varying modulating singnal should be done
>previous to modulation. This is sometimes done and some
>transmitters include audio AGC circuits or clippers.

I don't believe that the TR-7 has any audio AGC or clipping, the only control point is the ALC-driven attenuator on the @nd IF/Audio board.

> All amplitude
>or frequency processing is "distortion" in that the signal
>following it is different in some way from the original

Brilliant! I've known this for years, just as I've known that the MP3 computer format is intentional distortion. You should see the looks I get from self-professed "audiophiles" when I tell them that. Heehee.

>sometimes this "distortion" is benificial. It can be
>overdone as a survey of local broadcast stations, especially
>in large markets, will rapidly demonstrate.

I was told years ago by an engineer that radio stations adjust their audio to sound good on a cheap in-dash car speaker. This was before hi-fi car stereos. He even mentioned an AM station he worked at that had an actual car radio and speaker mounted in the equipment rack as a monitor.

Great stuff, Richard, thanks for jumping in. This is probably going to get Paul all fired up again! :)

Hi Jim N0UC,

Again, I'm not going to resend all that went before, so I'll simplify <grin>. Just be aware that it took 4-hours to write this <grin>.

I checked SM5BSZ's website. No mention of TR-7 ALC specifically, unless it was a comment in one of his unrelated articles. But that's quite all right. Any ALC that works is not "abominable".

As for the FCC mandating compression limiters to mitigate the use of power mics; we do well to have some historical perspective. There were no power mics on the market for several years after the original creation of the CB R&O from the FCC (and not many even in the HAM community [compression? What's compression? I don't need no steenkeen compression, I got ALC <grin>]).
Remember the average modulation spec, I spoke of? The FCC knew (figured out after the initial R&O) that without some kind of limiting and compression, the average modulation would be at the mercy of the person speaking into the mic. In those days, CB radios were pretty crude (Johnson Whiteface anyone <grin>?), and all were Carrier AM. This leads us to the expanded CB R&O some years later, which required the compression/limiters. Some years after that, makers came out with power-mics, etc. Power-mics were a lousy idea, when by then, the compression/limiters were quite good, and the radio was not "improved" by the use of extra amplification at the mic circuit (as you well know).
Even with the compression/limiters in place and working; with enough amplification, the user was able to totally saturate the internal mic-amp, and splatter the thing into three colors of distortion (mostly blue for our bruised hearing <grin>). Hence the progression into "... the problem is the compression/limiter, so we'll get rid of that ...". We know where that went, IMD, harmonic products, channel overlapping, and an overall destruction of the entire CB frequency spectrum in some locales, because of the basic increase in electronic noise. Thank GOD CB as an excuse for stupidity has given way to less abuse, over the last 30 years.
There was some attempts to make useful mic products. The Turner +3, comes to mind. Even used on Ham Tube rigs, this mic was one of the few useful exceptions. And almost useful in the CB community, few users of the +3 were the kind of folks that cut the limiters out of their CB radios (thank God).

RF Speech compressors. If I had to tell the truth, I'd have to say that I prefer a well designed audio compressor, versus the RF speech compressor. The circuits are simpler, they need less alignment, and the circuit is similar in capability. For example, TenTec has a RF Speech Compressor for $250, but they also used-to make an audio speech compressor kit that could make 6db of compression for less than $15 (I have one of these)!
But I'm aware that many folks want a compressor that provides time-domain output that resembles a square wave, which explains why there are some folks that can't understand why we can sometimes hear the wifes' mixmaster in the background when some folks crank compressors up too hi <grin>.
Because it is difficult to get distortion out of a properly aligned RF speech compressor, they've been a very strong inducement to excessive compression (you and I both have

mentored people in getting them to turn down the compression in order to reduce the background racket, and still get meaningful average talk power <grin>, of course this means lowering the compression level to the range any audio compressor can manage).
I tend to like the fact that an audio type compressor will usually go into distortion before background noise becomes REALLY objectionable. I like to think of it as a failsafe. The user can hear excessive compression distortion in his radios' monitor function, and that helps us all (this assumes of course, that the user is sane and reasonable <grin>).
But in even more general application, compressors can even be objectionable when they ARE set correctly. You recall how many people have to shout to overcome the sound of their tabletop amplifier fans <grin>. The same guy who has the $6000+ to buy the amp, thinks $300 for a low-signal noise gate clamp is a poor use of money. Go figure. No compression. Mild compression. Excessive compression. Everybody, that has one, gets to choose.

E*E/R is great formula for Power. E*I also for Power. Power formulas, Shpower formulas. They only work with a proviso. The formula is only valid for a single waveform. Everything BUT modulated carrier AM can be assessed via these simple Ohm's Law variant formulas, in one step. But modulated carrier AM is composed of three simultaneous waveforms. This fact makes common usage of power formulas (common for other modes) totally useless, unless we go to some extra effort to break out each part of the signal and interpret them individually.
I never tried to imply that the math by itself was of no use, but math always become useless if we try to use it with the wrong assumptions for inputted data. I was making a case for throwing out the math, because we can test my point with instruments, and find that common usage of Ohm's formulas for Power, are wrong for Modulated Carrier AM. I was trying to get people to re-assess the assumptions. Physical facts, trump the answers gotten from misused math, every time.
Let's look at modulated carrier AM another way. If we look at the AM waveform (with a 1-Khz modulation) in a oscilloscope, normally showing voltages over the time domain, we see only the modulated wave impressed on the carrier band. This does NOT show us a true representation of the structure; only the peak voltages, and the relationship of signal to carrier versus the available power supply. We WANT to see this, if we are calibrating a transmitter, in order to get full saturation without distortion or IMD products. But this is totally useless for making a good calculation for POWER.
To do that, we need a spectrum analyzer. A spectrum analyzer is a oscilloscope that operates by frequency, instead of time. The spectrum analyzer shows us what a properly calibrated, and modulated carrier and sidebands looks like as spikes in the frequency domain (it turns the O-scope waveform on its' horizontal edge 90 degrees). What we see is the negative sideband (half the height of the carrier). The carrier. And the positive sideband (again, half the height of the carrier). This means that the minus sideband is 25% of all power, carrier is 50% of all power, and the positive sideband is another 25% of all power. 25%+50%+25%=100%. This means that a radio that CAN produce 100-watts, and has a AM carrier of 25-watts, will PEP at 50-watts. 12.5+25+12.5=50-watts.
Now we can make an intelligent assessment of power for AM. You cannot use a single waveform to interpret AM, because there are more signals than one. It doesn't matter how you get there, a carrier at 25% power is completely wrong, given good design and a sufficient power supply. There is nothing magical about AM versus FM carriers, or CW for that matter. If the given transmitter can make 100-watts, then by using our eyes with our spectrum analyzer, carrier is 50-watts, and the sidebands will calibrate out at 25-watts a piece. That's 100-watts. The power formula works, but only IF we know the relationship of the carrier to sidebands. Without that, we get weird assumptions like 25-watt carriers in 100-watt radios.

"PEP is defined in Federal Standard 1037C". Correct, for a single waveform. But modulated carrier AM, is not a single waveform, making all previous assumptions correct if we assess all waveforms in the AM signal SEPARATELY.

Let's look at your discussion of TR-4 AM (or the really weird approach [as you say] of the tr-7 AM). If we are unbalancing the modulator, to produce a carrier, and then mixing some audio with it, we will get one sideband,and one carrier. In this example, it would be just fine to continue with 50% carrier, and then 50% for the existing sideband modulation (as long as we understand that a diode detector receiver will AGC at the wrong point, and the audio will be a little loud). But that's not true Carrier AM, it is a simplified variant, missing the other sideband. If it is NOT missing, then both sidebands are 25% power EACH. The composite potential always comes out 100% Power.
Let's get really weird, and look at a normal audio voice waveform. All composite frequencies, within each sideband envelope must share 25% power, for each sideband. Some of these sounds will get pretty small, by power. As you say, you can't get something for nothing. The sidebands, regardless of their structure, are ALWAYS 25% power, EACH.

All of this discussion leads us to a very interesting conclusion. SSB signals are much more power efficient than modulated carrier AM. Now we see why. Not having to give power to the carrier and one sideband, all available power can be sent in the output sideband. In fact, we could reasonably say that SSB is 75% more power efficient. We knew this when DSB, and then later, SSB radios were invented. It is a shame that these common sense facts have been distorted by poor reasoning, and actual FCC rules on the books (like 375 watts carriers for AM 1500 PEP [total nonsense]).

Again lots of fun, thanks Jim!

From: facsmart
Topic: 6029 Message: 6029

Ok, now that the S meter issue is resolved I have a new one. I am attempting to tune the rig, I have followed the manual, but the Xmtr gain has no effect, will not rise above idle current .1. Plate and load at 0. I am stumped. What am I doing wrong?

Minor corrections...

Unbalancing the Balanced Modulator to produce a carrier, and then mixing some audio with it,
produces TWO sidebands and one carrier. The selected crystal filter determines which one is transmitted in SSB.

The TR-4 generates AM by unbalancing the Carrier Oscillator. It is then shifted ~900 Hz to put it
within the LSB filter, mixed to the desired band and amplified. The AM modulation is 'controlled
carrier' of the Driver and PA, a form of Screen Modulation that I think came up earlier in the
discussion. The amplitude of the carrier varies with modulation, rising only high enough to support
the modulation applied, making it much more appropriate for use with a linear amplifier. There is
NO ALC applied in AM. The T-4X(any) use the same system.

As Jim said, the TR-7 uses an entirely different scheme for AM, which he has described.

Again, I don't recall that compressors were mandated. I'd like to see a citation on that. Limiters were. And power mics were available before lmiters came into common usage. But this is a digression from the original topic.

> There was some attempts to make useful mic products. The Turner +3, comes to mind.

Agreed on that. I generally detest preamped mics where they are not needed, and I remove the amplifiers from Astatic T-UGx stands. But I tried out a +3 on my rig one time just as a lark, and it edged out several other respected mics in audio checks with locals who know my voice. The fact that the SP-75 also has a little bit of audio compression does not seem to cause problems with gain settings at sane levels.

>RF Speech compressors. If I had to tell the truth, I'd have to say that I prefer a well designed audio compressor, versus the RF speech compressor.

The ones I'm thinking about apply compression in audio, clipping in RF. It is documented that RF clipping is the most effective method of improving intelligibility over log paths, over audio compression and clipping. Audio clipping is a no-no because the harmonics can't be dealt with easily, and you've addressed the problems with over-compression.

> The same guy who has the $6000+ to buy the amp, thinks $300 for a low-signal noise gate clamp is a poor use of money. Go figure.

FWIW, the SP-75 has a noise gate built-in. Should be worth $300, no? :)

No compression. Mild compression. Excessive compression. Everybody, that has one, gets to choose.
>
>E*E/R is great formula for Power. E*I also for Power. Power formulas, Shpower formulas.
> They only work with a proviso. The formula is only valid for a single waveform.

Exactly! And that's what makes you right, Paul. You are absolutely correct that the sidebands are 50% of the amplitude, or 25% of the power, of the carrier at 100% modulation. If you do the calculations at that level. But that's not the way we do things. We look at the composite waveform, which is what does the work for us. Even SSB voice is a composite waveform, but we don't break out all the individual sideband frequencies to calculate power, we measure the composite waveform.

Each sideband is 50% of the amplitude of the carrier. E^/R tells us that the power is 25% of the carrier, for each sideband. Again, that's taking each

component as a single entity. Good. You are correct. But what happens when we add them together into a composite waveform? We don't add power, we add voltages. At some point, the voltage at the peak of the waveform in both sidebands (talking single-tone modulation for simplicity) will line up, or be in phase with if you will, with the peak of the carrier. 100% + 50% + 50% = 200%. There, we have our doubling of the votlage. At some other point, the peak of both sidebands simultaneously will be out of phase with the peak of the carrier. 100% - 50% - 50% = 0. At various other points throught the modulation cycle, the sidebands add or subtract in different ratios. Congratulations, we have just produced a modulation envelope! This is what we see on our scope, what our envelope detectors respond to, and I dare say what we hammer our resonant antennas with. And doubling the voltage quadruples the power. Nothing magic about it, just physics. You can't invalidate the power formula in one circumstance and expect it to hold true everywhere else. You really can't have your cake and eat it too.

Things change when you have only one sideband in AM SSB. If we limit the amplitude of the sideband to 50% of the carrier, as in DSB AM, we can only achieve 50% modulation. Therefore, the amplitude of the sideband must be the same as the amplitude of the carrier to get to 100%. The same reasoning regarding the phase adding and subtracting to create the modulation envelope in the time domain applies here.

> that the minus sideband is 25% of all power, carrier is 50% of all power, and the positive sideband is another 25% of all power. 25%+50%+25%=100%. This means that a radio that CAN produce 100-watts, and has a AM carrier of 25-watts, will PEP at 50-watts. 12.5+25+12.5=50-watts.

You do have a slight math error there. The sidebands are 50% of the voltage amplitude of the carrier, or 25% of the power level, true. But that is referenced to the carrier as 100%, not 50%. As you know, the carrier amplitude on a spectrum analyzer doen't decrease when sidebands appear. It stays at that reference level. So you are adding the sideband power to the carrier power, and that makes 25% + 25% + 100% = 150%. Using the proper math by shifting our reference to the total power level of 150% of the carrier, the carrier would be 66% of the TOTAL power, the sidebands a combined 33%. That's not quite right either because it ignores the fact that power increases as the square of the voltage, and you keep talking about power. But we'll go with it for now.

Using the AM SSB example above, if we eliminate one sideband, the have to double the voltage of the other sideband to produce 100% modulation. That means power increased by a factor of four. That means for your 50 Watt carrier we would need - wait for it - a 50 Watt sideband! That evil square sneaks in there again.

> Now we can make an intelligent assessment of power for AM. You cannot use a single waveform to interpret AM, because there are more signals than one.

Sure you can. It's called a composite waveform. Look at it this way: a square wave is a composite waveform of a sine wave and a bunch of it's harmonics. We can sure see that on a spectrum analyzer. Yet everyone knows that the RMS value of a square wave is the same as it's peak, and that it will produce the same

amount of power in a resistive load as a DC voltage of the same level. There's no magic server pixie dust that changes the laws of physics from on kind of composite waveform to another. Not that I know of anyway, snake-oil magnetic power generating gadgets notwithstanding.

>modulated carrier AM, is not a single waveform, making all previous assumptions correct if we assess all waveforms in the AM signal SEPARATELY.

We don't. That's whe point. We measure the composite waveform.

>
>Let's look at your discussion of TR-4 AM (or the really weird approach [as you say] of the tr-7 AM). If we are unbalancing the modulator, to produce a carrier, and then mixing some audio with it, we will get one sideband,and one carrier.

No, we get two sidebands with a carrier. One sideband is removed by the crystal filter. The carrier in the TR-7 is re-inserted after the crystal filter. So it's not really the same as the TR-4. The BM stays balanced, and the carrier oscillator is snuck back in through the side door just before we hit the kitchen. It works out about the same, ignoring the controlled carrier stuff. It looks like a duck and quacks like a duck, albiet with only one wing.

> In this example, it would be just fine to continue with 50% carrier, and then 50% for the existing sideband modulation (as long as we understand that a diode detector receiver will AGC at the wrong point, and the audio will be a little loud). But that's not true Carrier AM, it is a simplified variant, missing the other sideband. If it is NOT missing, then both sidebands are 25% power EACH. The composite potential always comes out 100% Power.

33/66%, remember?

> Let's get really weird, and look at a normal audio voice waveform. All composite frequencies, within each sideband envelope must share 25% power, for each sideband. Some of these sounds will get pretty small, by power. As you say, you can't get something for nothing. The sidebands, regardless of their structure, are ALWAYS 25% power, EACH.

No, each sideband is at a power level of 25% as referenced to the carrier level. They don't steal anything from the carrier, it's still there. We calculate power from that same formula you wanted to throw out. The reference level doesn't change. I think that works out to 16% of the *total* power in each sideband.

A 100 Watt carrier and 25 watts in each sideband = 150 Watts. 25/150 = 16.67% of the total power is in each sideband. Holy cats, that's a 6:1 ratio! This gets better as I go along! 1500 / 6 = 250 Watts. If we go by the original 4:1 ratio that E^2/R on the composite waveform proves, 1500 / 4 = 375 Watts. Where have I heard that before? That's more like what can be arrived at empirically.

I think you can see why we don't add power, we add voltages. I don't think that anyone would disagree that if we could somehow capture a single cycle of the composite waveform at the peak of the envelope, we would see a sine wave at an RF frequency. If we then applied that sinewave to a load, we would have a single cycle burst of E^2/R power in that load. That doesn't change if we capture a bazillion cycles of the composite waveform.

>All of this discussion leads us to a very interesting conclusion. SSB signals are much more power efficient than modulated carrier AM. Now we see why.

Yeah, 6:1. Wow. I need a bigger antenna....

6034. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-13 20:29:19 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 6034

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

6035. Re: TR-4 No output No Xmtr Gain

From: facsmart
Topic: 6029 Message: 6035

I have an update, I cleaned the Cal/SSB/xCW/xAM switch, what a pain to get to. I now have output, I will have to clean the xmtr gain pot, I have the good deoxit coming this next week.

Now to get the AC hum out of the transmit.

--- In DrakeRadio@yahoogroups.com, "facsmart" <facsmart@...> wrote:
>
> Ok, now that the S meter issue is resolved I have a new one. I am attempting to tune the rig, I have followed the manual, but the Xmtr gain has no effect, will not rise above idle current .1. Plate and load at 0. I am stumped. What am I doing wrong?

6036. For Sale: Drake MSR-2 Communications Receiver

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-14 00:48:13 UTC
From: pidxr
Topic: 6036 Message: 6036

For Sale: Drake MSR-2 Communications Receiver with manual. Excellent physical condition. All nixie display tubes are fully functional and brightly lit. Jim, W8ZR has an excellent write up on the MSR-2 receiver if you are not familiar with it. Here is the link

http://www.w8zr.net/vintage/receivers/MSR2.htm

Here are some pictures of this MSR-2 receiver.

http://home.comcast.net/~bipi/sales/msr2_frt1.jpg

http://home.comcast.net/~bipi/sales/msr2_frt2.jpg

http://home.comcast.net/~bipi/sales/msr2_frt3.jpg

http://home.comcast.net/~bipi/sales/msr2_frt4.jpg

http://home.comcast.net/~bipi/sales/msr2_frt5.jpg

http://home.comcast.net/~bipi/sales/msr2_back.jpg

http://home.comcast.net/~bipi/sales/msr2_top.jpg

http://home.comcast.net/~bipi/sales/msr2_bot.jpg

http://home.comcast.net/~bipi/sales/msr2_fil.jpg

The radio is fully functional on AM. However, there are problems with the product detector and it does not operate on SSB or CW. There are several charred components on the IF/AVC board which can be seen on the following pictures. I just don't have the time for this project.

http://home.comcast.net/~bipi/sales/msr2_ifbd1.jpg

http://home.comcast.net/~bipi/sales/msr2_ifbd2.jpg

http://home.comcast.net/~bipi/sales/msr2_ifbd3.jpg

Price is $400 plus shipping from 98040. Prefer local pickup. Please contact me with any questions.

Thanks

6037. For Sale or Trade: TR-7, Extras.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-14 04:31:20 UTC
From: Ed WA4NJY
Topic: 6037 Message: 6037

Have a very clean TR-7 with a few issues. Includes 7077 desk mic, 1.8kc and .500kc filters, fan, power cable, original manual.

The issues:

1. UP button is not working.
2. Mic gain needs to be 3/4 open for full meter deflection. Audio reports are good.
3. Display reads about 200 cycles low.
4. One small knob has missing insert.

Otherwise, it has made several contacts recently. I will be using it on 10 meters now.

Looking for offers or suggestions on value. Will consider trades involving other HF rigs or Drake R4-A or B.

From: Kris Merschrod
Topic: 5975 Message: 6043

I woke up to the same problem today, and had it before.

1) the first time was that my ISP (local family-run company), it turned out that they have to go through Verizon's system and Verizon put a stong arm on them (and did not notify me that I had to) so that all outgoing needs to go through Verizon, but to do that you need an email account that uses SMPT

At the top of your windows mail go to TOOLS, then ACCOUNTS; then PROPERTIES; then SERVERS; and look at the " outgoing mail server"; then click SETTINGS an in there look at or for " Use same setting as my incoming mail" or if tghe second button is checked " Log in Using" see if your user name and password are corrrect.

Why that last section " Log in Using" was blank this AM I do not know, but once completed with the Verizon info, it sent again.

6044. e-Mail Outage

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-15 15:24:24 UTC
From: Garey Barrell
Topic: 6044 Message: 6044

Thanks to all for responding to my test messages sent yesterday.

The problem was at my ISP (Earthlink) and while I was able to send mail, no mail was received
between about 1100 and 1700. My test message was to SEE IF my mail that went out, really went
out.! I could then check the Yahoo group Messages and see that the message sent to the list WAS
actually there.... :-)

Anyway, all is well. My e-mail actually goes through Verizon in Richmond, to Mindspring in Atlanta,
to the internet. I do this to keep my mindspring address.

From: Paul Horvitz
Topic: 6045 Message: 6045

Thank you all for the ideas, It turned out those molex pins in a way.
When I had the translator board out the last time after reading the comments/ideas left on the group here, I noticed marks on either side of chassis where the board touched shield as it slid into place were not vertical. I'd inserted the board at a slight angle so the pins on molex were not in their proper spot but rather up against the PCB of translator. Shorting to ground some of them. Funny thing is I'd reinstalled it over and over while trouble shooting and didn't notice till it was mentioned about the molex pins in this great Drake group here.
Got 10v reg, 5 v reg now all OK, no transistor heating...now on to the next problem with this TR7 of mine! No Rx 10v going to 2nd IF/audio board. I'll start on that in a day or two, life gets in the way of hamming fun sometimes!

Thanks again everyone,
73,
Paul

From: William Garrett
Topic: 5964 Message: 6046

Sorry for the long delay in responding. I got tied up on another project on the farm.
The name is William, WB1KER.
Zero experience with tube radio gear. Taking it very slow and trying to learn as much as I can. I am restoring an old 1939 Hallicrafters SX-24 to learn more about theory, etc.
The mic is giving me fits. I found
several schematics on the web but none of them match my mike as far as color codes go.
Next is a pic of the schematic. Top is the schematic, bottom is what I have. Similar but withan additional Green wire and the insulator between #2 and #3.
The yellow from the head was broken loose from the switch. I soldered it back to #2, the center wire of the shielded wire, as per the schematic. I do not get a short between the shield and any of the other wires when the mic is keyed.
There are two wiring options on the schematic. One for Relay operation, one for Electronic Switching. The Relay option more closely matches what I have, with the exceptions, an insulator between #2 and #3 and a Green wire connected to #3, that I have drawn in. Which should I be using with the Drake?

#1 Shield#2 White (center of shield)#3 Green#4 Red#5 Black
#2 and #4 actually contact on the outer end so that when the switch is pressed,both arms move simultaneously, unlike the schematic. It looks as if #1 and #2 areshorted until the switch is pressed. Then contact is made between #4 red and #5 black

I didn't see a name on your email, so can't do this "personally" but welcome to the group. The RST on your connector stands for Ring, Sleeve and Tip. The Drake manual will show you to hook the shield to the S terminal or the sleeve (the longest metal part) of the connector. Whichever wire is the PTT (push to talk) hooks to the Tip (of course, the very end of the plug) and the audio lead from the microphone element hooks to the Sleeve (the little ring between the ring and the sleeve). You can locate the PTT lead easily by hooking one lead of your ohmmeter to the shield, and see which other wire shows a short only when you push the PTT lever or switch.
The
other one is the mic audio. Also mic audio is often inside the shield wire if you look closely, and is often white in the old microphones. I don't know the 619 EV mic, but Google it and you will find the wire colors if you can't follow the above.

That said, tell us your knowledge level with tube gear. You can DESTROY the final tubes in our T4XC transmitter if you aren't familiar with tube gear tuning. I don't mean to "talk down" to anyone, but these are TV sweep tubes and are NOT forgiving to abuse.

Again, welcome to the group, and hope you enjoy your C Line. If it needs any TLC, give a look on Garey's website at his CD for the Drake C Line (www.k4oah.com). It's a WEALTH of knowledge for these old rigs.

Paul -

Cool! Yes, it's all too easy to 'miss' the pins on these cards. Little visibility, and it 'feels'
about right! :-)

For your missing 10R signal, start at Q307. This transistor doubles as a fuse for the 10R line, and
even a momentary short will take it out.

10R goes into the Translator board on Pin 15, so it's quite possible that it got zapped at the same
time.

6050. Re: [DrakeRadio] Microphone Hookup Assistance Please

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-15 21:36:44 UTC
From: Don Cunningham
Topic: 5964 Message: 6050

William,
From your schematic, disreguard the green wire and the insulator does nothing to worry about. I would wire as follows:

1. Hook the red wire to the "T" (Tip) on the connector for PTT

2. Hook the white to the "R" (Ring) on the connector for audio

3. Hook BOTH the shield and the black wire that is left to the "S" (Sleeve) for grounds for both audio and PTT

This way, when the button is pushed, it grounds the PTT line and you can transmit because the PTT line will be grounded as Drake requires. ONE BIG problem though is you can NEVER use VOX this way, as the element is grounded when the ptt lever is not pushed in. Looks to me like the insulator is in the wrong place for using VOX (electronic keying likely in their drawings), as you would want the insulator between pins 1 and 2 then tie BOTH the green wire and the white wire together for audio to work both for VOX and PTT. If anyone else reads this differently, PLEASE chime in. I only jumped in because William was getting no help at all.

Paul -

I don't know of a direct replacement for the 'wired in' relay in the "B". Drake sold a 'kit'
consisting of a small PC board and relay socket to accept the P&B R10-E1-Y4-V2.5 relay used in later
models. Unfortunately, those are no longer available. I have reworked an artwork for the board,
but the project got put aside. The board is essentially a way to spread out the very tight relay
socket connections to terminals around the edge of the board. There are a LOT of wires going to that
relay, and of course the wires involved are all the extremely heat sensitive hook-up wire used by
Drake, so anything that 'spreads' them out is helpful. Another list member made a simple bracket out
of PC board material to accept the relay socket, but I haven't heard back re a 'final' installation.

The B-Line relay is only a three-pole double-throw type as opposed to the 4PDT in the newer models,
and it may be possible to select a wired-in relay from Mouser, Digi-Key, etc., but the enclosed,
plug-in relay is a nice thought! :-)

Let us know 'your' solution.

6059. TR7 Troubles wrap-up

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-16 16:07:16 UTC
From: Paul Horvitz
Topic: 6045 Message: 6059

Garey,
The board sure did feel right while plugging it in. I could feel the pins being grabbed and a slight resistance while sliding it in as those wipers inside the connector made contact. Hopefully a live and learn experience!

The TR7 is new to me and I'm enjoying getting to know it, don't understand the complaints I hear others have about the boards being plug in, I like the construction of this rig. Always wanted one, when they first came out they were too expensive for me though. Used to have both the B line and C line, liked the B line better really, for casual rag chewing on CW and SSB, which is mostly what I do when on the air and not fooling with rigs or antennas.

--->Transistor Q307, a 2N4402 has a shorted junction on it! Thank you, I hadn't even begun reading up in the service manual about how that 10v Rx voltage got switched, came to be, etc. Probably would have spent hours reading before I discovered it's on the Tx driver board so you saved me much time with that. I poked around measuring a few other components in associated circuitry and all looks well.
So now I get to go out to the storage shed, finally organise the transistor collection out there and while I'm at it, look for a good one to go in the TR7.
Wish my Huntron Tracker still worked! That was such a sweet diagnostics tool once I'd learned to interpret the "signatures" I'll have to repair/replace it. The CRT went south. Have to find it first...storage shed again.

I'll post again when that replacement transistor is soldered in and let you know the results, in 5 or 7 days.

73,
Paul

I have one with a slight bend in the frame because someone shipped it to me with an AC-4 still screwed inside! Price : $35. If you want one in great shape I have it for $90. Have others in between. You pay shipping or pick up. Just moved and had no idea how much Drake stuff I have collected over the years until I had to pack it. Am thinning the herd.

Paul -

Yeah, they're pretty tricky! :-)

The only problem with the plug-in board system, especially in solid-state gear, is that only a minor
corrosion on a pin can kill the radio. I'd say that probably 90% of the 'broken' TR-7s can be fixed
by unplugging and replugging the boards and cables to get through that oxidation. You will not find
plug-ins on any piece of critical equipment unless they are absolutely necessary. At NASA 50+ years
ago any connectors that HAD to be there were gold plated, hermetically sealed, etc., etc. We only
put connectors where there was NO other option. I don't recall the exact number, but something
like every connector interface increased the failure rate by a fractional percentage.

I prefer the B-Line as well. It's not going to survive in the middle of a low band contest like a
C-Line will, but you can listen to the B audio all day without getting a headache! I also prefer
the gentler slopes of the L/C filter as I like to know what's going on around my frequency.

Those 10R and 10T switches are cleverly tucked away! Probably one of the last three or four places
you would be inclined to look for them. A 2N3906 will work fine in place of the 4402. Most any PNP
switching transistor will do. Watch for possible lead arrangement variations.!

That's just another reason chalked up to us needing the "TR7 troubleshooting notes from Garey" CD or paper version, AND I'll still volunteer to buy the first set, hi hi. You seem to "know" all these little hints that we have to read hours to find. Oh well, I've bugged you enough about that.

We SHOULD tell Paul of the nice extender board set offered by one of our list members that makes troubleshooting MUCH simpler. Bob Rolfness, W7AVK, makes a nice seet MUCH cheaper than the "original" ones that prices are skyrocketing on "the auction place". Bob can be reached at rsrolfne@... . No connection, except to say that the boards are first rate and are a real help in working on these things.

6064. Drake TR-7 CD

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-17 19:35:18 UTC
From: Garey Barrell
Topic: 6064 Message: 6064

OK, I'm weakening..... I keep getting requests for a CD for the TR-7. I'm really not sure why,
since the Drake Service manual is more than adequate for servicing these radios.

There were 'lots' of requests for a CD for the R-4A / T-4X pair a few years ago, and against my
better judgement I developed TWO CDs, one for each of the drastically different models of the R-4A.
Approximately 20 copies have sold of both combined. So you can see why I'm a little gun-shy! :-)

So. Being a little smarter (not much, I'm typing this...,) I'm asking for input on what YOU think
should be included in a CD for the TR-7. The Drake manual already has complete parts lists, and
photos of the boards with parts keyed to the list. Since I see this as the central value of MY CDs,
I'm coming up short for something to differentiate MY CD from Drake's manual.

Of course the other question would be what price range would you expect this CD to be in? The Drake
Service Manual sells for about $50 these days, and there is an aftermarket CD version for about $10
and a print version for about $20. Consider that making a CD similar to the 4- Line CDs would
require pretty much complete destruc.... er, dis-assembly of a TR-7.

Thoughts?? Direct to <k4oah@...> please....

Thanks for the tip on those extender boards Don. I looked for some a while back, deemed them too pricey (at that big $$$ auction web site I have a love hate relationship with) at the moment. Will look into these you mention.

I got impatient waiting for those 2n4402 transistors to arrive so dug through "spare parts" junque pile and found some suitable replacements in an old telephone answering machine, scavenged them and installed in my TR7. Now have 10v reg Rx runniing, AGC, Rx audio etc. !!! Am going to pad the headphone jack...way too much audio going to my sensitive head phones, do a mod to give more vox gain as it has to be cranked up all the way and is still not enough, then put the rig back in service, hopefully today.

Paul,
Drake put a 100k resistor (or close) in their headphones in series with the "hot" lead to solve that volume problem. I usually put one inside the phone plug on my headphones so the rig is unmodified. Works either way, but the next owner may have different headphones and work a long time to figure out why they don't work. Just Don's way though, not necessarily right, hi.

That should have been explained in the instructions, as I got it all installed and found I had the extra part. I toasted that board getting it back out, I order another, and in the mean time I bread boarded a new board for the relay.
Thank you, I will remove the choke.

Ted -

It's been a while since I did one of those..... I had to go look at the Drake instructions, which
come with the board, to remember that RFC. I agree, it should have been specified.

Have two desk mics for Drake TR-7. Both work right and look very good. One has slightly darker PTT buttons. $75 for the white button one, $70 for the other, plus shipping. They will be packed well.

That's a great adventure Ted.

The next step is to find out WHERE The signal is disappearing. Possibly test all of the tubes
first to make sure nobody died.

Use an audio signal tracer and go back through the audio stages. Got anything there at the volume potentiometer?

Work your way back to the detector.

After that, as you delve into the detector and the i.f. stages, mixer etc. you are going to need
an RF detector of some kind. It can be a simple diode and resistor. ^here are some simple designs for an RF detector, that will turn it into audio for the signal tracer.

Tune in a strong AM station. Start poking. Problem should be easy to localize. BUT also check your AGC voltage to see if it is throttling everything back to low gain.

From: Gary Woods
Topic: 6081 Message: 6081

What should RF levels in and out of the selectivity (filter) board be on
CW, key down, normal output?
Tx is 20W max out, and Rx is proportionately punk. Datapoint: I put in
the optional AM filter several weeks before the problem appeared. I've
reseated modules in the area, including RF switching (I don't have the
noise blanker).
TIA,

6083. CW Offset using Drake C-Line Twins

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-22 03:29:18 UTC
From: k4swisscheese
Topic: 6083 Message: 6083

Hello group. I joined the group and searched the articles hoping to find some guidance, but so far have struck out.

Here is my situation. I just purchased an R-4C, T-4XC and MS-4/AC-4 combination. I am putting these on the air, temporarily side lining my Elecraft K3. Being primarily a CW operator, I am used to having a side-tone set about 500 Hz; I found the 1 kHz sidetone too high pitched but knew I couldn't readily change it. For my first CW contact I was controllin both transmit and receive frequency with the R-4C VFO. I answered a CQ and had tuned to my normal preference of about 500 Hz ±. When the station answered me, he had moved and was now about the same as the higher pitched sidetone. Easy enough to figure out he had adjusted his frequency for a "normal" pitch in his receiver.

I didn't want to do the VFO waltz down the band, so I switched the VFO control to the T-4XC and adjusted the receive to match the tone I was hearing from the R-4C VFO. I then switched to separate VFOs and adjusted the R-4C to a reasonable tone and completed the QSO.

I go into excruciating detail to illustrate why I am seeking a simpler solution. I guess it's been too many years since I zero beated a transmitter VFO, and wonder if I do that if I still won't sound off frequency to the other station. Is there an easier solution, if so I'm all ears! Anyone have suggestions?

Thanks! Chuck K4SC South Carolina

6084. Re: [DrakeRadio] Drake TR-7 on AM question.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-22 04:44:58 UTC
From: Paul Pollock
Topic: 5975 Message: 6084

To Jim Shorney N0UC,

1). Compressors were not mandated, only an average modulation percentage. How a user (or manufacturer) got there was HIS problem <grin>.

2). Speech Compressors
Whether RF speech compressors are more effective is a generally accepted conclusion with provisos. Is there a noise gate? Or is the acoustics of the studio quiet? If its' not, intelligibility will suffer. In normal practice; too much of a good thing is possible with a RF-speech compressor, it's just as much of a mistake as wrong use of an acoustic compressor. I just prefer the one that can be detected under abusive conditions easier. RF-speech compression is harder to tell for acoustic abuse, but the listener still has to deal with aunt Mary's mixmaster <grin>, just the same.

3). "You are absolutely correct that the sidebands are 50% of the amplitude, or 25% of the power, of the carrier at 100% modulation."

Wrong, Without the RF Power from a transmitter, there is no amplitude for a spectrum scope to measure. The Spectrum analyzer is showing us power, even though amplitude (which translates in this instance as voltage) is used for the waveform, because we are dealing with immutable math that dictates that a transmitter; that must operate at a given output impedance, at a given frequency, that operates in the ether, which produces what appears to have a certain amplitude, must be generated by a given power level. It's not amplitude, its' POWER. E*E/R remember (also works with E*I)? To get apparent amplitude to rise, with a fixed impedance and voltage (as we see in most transmitters), current must rise; which produces the requirement for an increase of total POWER (explains why the only difference between an FTDX-9000D and FTDX-9000MP transmitters, is power supply current.

I never said amplitude, you did, and are quasi-wrong for using it. Amplitude is something to describe a graphic picture on an O-scope (and only from a relative standpoint), but it has no place in any other radio discussion. All spectrum Scope traces are showing power, I don't care whether we are looking at a transmitter waveform, or whether we are looking at the output of a signal generator; it all boils down to power. E*E/R (or E*I) remember?
I pointed out already that a oscilloscopic wave form is useful, but does not tell us the structure. Because it can't show structure, we cannot apply a formula properly. An O-Scope composite view, is an erroneous view, in terms of finding out where the power is. Without the spectrum scope view, we have no tools whatever, in doing anything like a relevant calculation. While your discussion here is relevant for amplitude, amplitude is not in the offing, there is no amplitude to discuss; only power.

4). "Each sideband is 50% of the amplitude of the carrier. E^/R tells us that the power is 25% of the carrier, for each sideband. Again, that's taking each component as a single entity. Good. You are correct. But what happens when we add them together into a composite waveform?"

This is totally wrong. The spectrum scope is using voltages to show a display, but these are not showing amplitude. Because this is a transmitter, we cannot separate the amplitude

from power, the spectrum scope is showing an accurate analogy for power. Carrier is 50% of power, and modulated waveforms indicated in the spectrum scope is also 50% (25% each sideband) of power, not merely amplitude.

More importantly, and in reality, a modulated AM signal is not a composite signal at all; the spectrum scope shows us this accurately. It cannot be evaluated as a composite, as to power. Moreover, the fact that a modulated AM signal is NOT a composite; explains very well, why we get signal phasing, and distortion in a received skip signal. The separate parts of the signal get affected by the ionospheric dynamic; at different rates, times, moments, and spectrum points. This causes the carrier-to-sideband ratios to change. Even the sidebands can become distinctly larger/smaller vs the other sideband; and is a major reason why SWL folks prefer a Sync-AM detector system (when available) with selectable sidebands.

5). "Things change when you have only one sideband in AM SSB. If we limit the amplitude of the sideband to 50% of the carrier, as in DSB AM, we can only achieve 50% modulation. Therefore, the amplitude of the sideband must be the same as the amplitude of the carrier to get to 100%. The same reasoning regarding the phase adding and subtracting to create the modulation envelope in the time domain applies here."

Limiting the relative amplitude (using your argument) to 50% of the carrier, is missing the point. I just said that if 100% power was desired, the outputted sideband(s)would be able to make up the difference owing from loss of a previously available component. If we are using TR-4 AM, if carrier is 50%, the output sideband can be 50%. In DSB, the carrier is missing, so each sideband can be at 50% of total power; this will not tax the power supply, and the outputted RF will be 100% design maximum power, without distortion.

You keep thinking about AM as a composite, and it's not. Each component can either be sent or not, or even filtered, as we do with SSB generation. SSB is begun by balancing the carrier, driving it out of balance at audio frequencies, and then stripping off one sideband (in most radios. Phase filtering was used in early SSB transceivers, and contained no sideband filters of any sort, that either of us would recognize today). In C-Class plate AM, we actually use the final amp to mix an equally sized modulator output to make carrier AM, but it's no great task to strip off any part of the components. If we can precisely strip off a sideband, it would be no trouble at all to filter the carrier and leave the sidebands untouched (without a balance modulator). This is because each component is actually at a slightly different frequency domain, but happens to normally be in sync.

Conversationally, it is easy to look at almost any multiple waveform as a composite (depending on how we choose to observe it), but it doesn't mean that a multiple wave form IS a composite, especially when it behaves unlike a signal composite.

6). "You do have a slight math error there. The sidebands are 50% of the voltage amplitude of the carrier, or 25% of the power level, true. But that is referenced to the carrier as 100%, not 50%."

There was no error. I was pointing out that if a given transmitter is capable of 100-watts, and is hobbled to 25-watts carrier, total modulated AM PEP is 50-watts. The hobbling is caused by misinterpretation of power, as if modulated AM signal was a single composite, and it's not. There is nothing wrong with the reasoning, only the usage of a good math formula with bad assumptions.

7). "Sure you can. It's called a composite waveform. Look at it this way: a square wave is a composite waveform of a sine-wave and a bunch of it's harmonics. We can sure see that on a spectrum analyzer.

A square-wave is an excellent example of a composite wave-form. As you know, everything that gets distorted begins to resemble it. That does not create a situation where all multi-component wave-forms are composites. That is a false conclusion.
A true composite does not get bent when transmitted in the ether. A square-wave of any construction, will skip (refract) off the ionosphere and basically stay a square-wave (including its composite parts if any), just as a sine-wave will. But three(3) separate components that just happen to be emitted at a slightly different frequency (as a modulated AM signal is), will not skip properly, that is a fact (as any SWL doing AM listening can attest).

The entire point of this discussion is that the usage of the power formula on a modulated AM signal as if it were a composite BEING IN ERROR is the point. You just think it is not in error.

8). "A 100 Watt carrier and 25 watts in each sideband = 150 Watts. 25/150 = 16.67% of the total power is in each sideband. Holy cats, that's a 6:1 ratio! This gets better as I go along! 1500 / 6 = 250 Watts. If we go by the original 4:1 ratio that E^2/R on the composite waveform proves, 1500 / 4 = 375 Watts. Where have I heard that before? That's more like what can be arrived at empirically.

I never suggested that, and you know it. A 100-watt carrier would need two(2) 50-watt sidebands, which would make 200-watts total PEP. There's no confusion here. 375-watts stays wrong, no matter how you want to get there. E*E/R is a good formula, when used right. But in the case of modulated AM, it continues into the future (as used today) completely wrong. 375-watts continues to be wrong, because of this constant error. 1500-watt total available PEP will allow a clean 750-watt carrier, with clean 375-watt sidebands.

This continues to be fun, Jim. Thanks for the stimulating conversation <grin>!

Wow, that one had me rolling on the floor. Really? That violates the laws of physics.

I give up, Paul. It's the composite waveform that does the work for us, and empircally matches up pretty well with that I've been saying. An awful lot of science and real world applications can't be wrong.

Here, Paul, is a page that puts your numbers in the proper context:

http://www.rf-amplifiers.com/index.php?topic=peak_power

It's got pictures, so everyone should understand.

It shows where your numbers are right, as are mine. Your mistake is in the math, and the assuption that spectrum analyzers are measuring power. They do not, they are a voltage display. Do you not understand how oscilloscopes work?

I weary of this game. See you around, it's been fun.

Hi Jim N0UC,

I read the page you sent me to. Correct for a carrier. I have no problem with their math, just your assessment of what it means. Not for modulated AM. There is no composite, looks like one on a O-Scope but is not. Laughing, rolling on the ground, does you no credit; you're still going to come out wrong on this.

I've dare'd college instructors to show me a waveform that demonstrates the composite modulated AM waveform, and they could not do it. Nobody can.

Until this stuff is air'd out correctly, modulated AM will continue to get short shift by folks like the FCC.

But, you are right, the conversation has gone down to he said, he said. Beside, it doesn't change my life in the slightest anyhow, I don't operate modulated carrier AM, never really wanted to. It was the discussion that mattered.

I just did, and so did the Empower web page. College instructors notwithstanding, the phasor diagram explains it perfectly. I suggest you go argue the point with the people that own that page. I'm sure their military, aerospace, and other customers would be very interested to learn that they are being sold a bill of goods. I'll wave when the black helicopters come for you.

I can't point out the errors in your math and assumptions any more clearly. You very cleverly skipped over some of my points, that says a lot. You can't change the laws of physics, you can't alter Ohm's law, you can't demodulate SSB with a spectrum analyzer, and you can't make 150%=50%. You say you don't operate AM, perhaps that's why you don't understand it.

Please direct any further discussion to the engineers at Empower. I'm sure they would love to hear from you.

You're gonna get a kick out of this, Jim.

http://forum.videolan.org/viewtopic.php?f=7&t=1163&p=4537

When it comes to how to win friends and influence people, our friend Paul has an M.O. with a history.

Hey, I hope you had fun with the contest over the weekend. Man, I can't stand the racket of all these contests every weekend. I think the only thing to do here is grab the bull by the horns and get involved!

I think I'll start by dropping in on the club station at VE6AO. I've seen their set up. That'll be some contest immersion for me.

6089. Low output power T-4XB

From: hglent
Topic: 6089 Message: 6089

I have been fighting a low output problem on my T-4XB. The maximum power output I have been able to get is 50 Watts.

I have Installed the WB8VGE kit in the power supply, replace all tubes 1 by 1, replaced finals with a "matched pair." Installed Hayseed Hamfest ReCap kit, set the Bias per Page 14, Prg A, in Instruction Manual, did "Adjustment of RF & Mixer Stages" in Instruction Manual Pg's 37-38, taken all voltage measurement in the Instruction Manual Pg 33. The only problem I have identified is in the voltage readings. V-5 & 6, Pin 2, -35 VDC, should be -62 VDC Bias. The low Bias Voltage is present on all bands. The final replacement yielded the same results.

I have run out of ideas. Any one have suggestions as to what I look at next?

Please contact me off list as I only get the list in Digest Format. I will be working on this over the holiday weekend rather than being out there buying a new rig for my XYL. hi hi!

Paul -

Couple of questions.

1. Are both V5 and V6 'lit'?

2. What are you measuring output power with?

3. Good dummy load?

4. Plate current shown at maximum output?

Information to gather. What are the values and condition of R32 and R33? Value and condition of
R36? Voltage on Cathodes Pin 3 of V5 and V6 in TUNE mode?

How are you making these measurements? The voltage
charts specify an 11 megohm input VTVM. Most solid state
DVMs will do. If you use a passive VOM it may load the
circuit. Power out can be tricky, you need a good,
non-reactive dummy load of the right impedance (50 ohms) and
a good RF volt meter. I was getting low readings from my
T4XB at one point due to the resistor in my MJF dummy load
having changed value substantially. Also check the condition
of any cables you are using, a bad connector or bad
soldering can cause a mis-match that will give you a false
power reading. Know what you are measuring!

To Jim N0OC,

Hi Jim,

Nobody is changing the laws of physics, aside from understanding that physics has very few actual laws. The drawings I've been staring at for decades misses the point entirely. Modulation on these graphics (including what we see on an oscilloscope tuned to the modulation) does not show us reality, or real physics. It is truly an optical illusion. The carrier is not in fact being bent. The phasor discussions are a means of quantifying an effect that does not actually take place.

You can prove this point for yourself, by increasing the scope clock to sync the carrier, then slew the display any way you wish. This filters out the effects of audio from the display. I defy you to find a curve in the carrier. The carrier does not change, although it is easy to get fooled by looking at a audio-sync'd scope display. The apparent overtone is caused by the modulated waveform becoming the only thing the scope can reproduce properly, what is left is an overtone.

This point is even more clear when we use a digital spectrum analyzer and slew the display horizontally 45-degrees. We now see all three traces (almost looks like 3d display [very cool]), during modulated periods, and can clearly see the carrier straight as rifle shot.

Test it yourself. You need to lose the thought that modulation modifies carrier, because it doesn't. Carrier is a constant (aside from controlled-carrier, but we're not discussing that) .

I said I don't do AM, I've done a lot of it in the past. Putting thoughts in my head, and words in my mouth, is beyond bad manners in order to shutdown a piece of logical conversation that you might get out of your depth with.

There is no magic, no misunderstanding, and only truth. Carrier is a constant, the oscilloscope is lying, and anybody can prove it to himself by doing my example(s).

While the illusion is a useful one, and one of the few ways to calibrate a AM voice transmitter easily, it is still an illusion. This illusion is the only reason why we get this tale from technical discussions that use the formulas we've been discussing in error. The text on websites all over the world, has perpetuated this myth forever, and amounts to a discussion to describe an exception, because voice AM is unique in voice radio. 70 years ago, even I would have believed it, because the O-Scope was literally the only tool available to see a waveform. But it sees darkly, because it only has one spot to place, and blanks everything else.

Empower would love to talk about this with me. I'd win. Nothing against them, but they've bought this baloney too, and tried to explain this with gobbledygook. Plain and simple. Everybody who's seen a AM trace on a scope has tried to explain this away with gobbledygook. To this day millions of people continue to believe the gobbledygook without testing the hypothesis for themselves ".. they're smarter than me, they must know what they

are talking about ..." Baloney. This stuff is wrong, and nothing can change that.

Now I'm going to return your favor. Grow up, test the hypothesis, and get some truth. Don't depend on others to do your dirty work, test it yourself. Until then, your just another one of the millions who've bought into a lie. Anything else is purposeful ignorance.

I agree with you, the military could very well be very interested in buying hardware based on a lie. However, I've seen their stuff; they don't use Voice AM, because we both agree, it's not very efficient. I frankly don't think any military on Earth uses Voice AM. But the civilian world does, and many station engineers would like to know what you think you know. They operate on reality, and discussions of phasor motion and acceleration; and all the rest doesn't react on them much. They KNOW carrier does not modulate, they KNOW carrier is half of all power, and they KNOW modulation is half of all emitted power.

I've already tested this stuff until my eyes went far-sighted <grin>. Now I wear glasses. Couldn't believe the conclusion, but it is inescapable. Carrier does not modulate, it is a constant, and the math people have tried to describe this process with is misused, and even the point they are trying to describe uses data that is an illusion, and a myth. That's the truth.

To Jim N0OC,

Hi Jim,

Nobody is changing the laws of physics, aside from understanding that physics has very few actual laws. The drawings I've been staring at for decades misses the point entirely. Modulation on these graphics (including what we see on an oscilloscope tuned to the modulation) does not show us reality, or real physics. It is truly an optical illusion. The carrier is not in fact being bent. The phasor discussions are a means of quantifying an effect that does not actually take place.

Here is F.E.Terman on the subject (1)
"The carrier wave is the same, irrespective of the presence3 or absence of modulation. Varying the amplitude of the radio wave mearely has the effect of generating the side bands, which are the art of the modulated wave that conveys the intelligence being transmitted. The carrier wave carries no information because it is not affected by the modulation." He then goes on to discuss the relative power in the sidebands. This requires reference to equations which are not easy to translate to text but essentially he states that at 100% modulation the power in the total signal will be 50% greater than that of the carrier so that one-third of the energy is in the sidebands.

1, _Radio Engineering_ 2nd Edition, Fredrick Emmons Terman, 1937, McGraw-Hill Book Company.

I think the same thing can be found in later editions and in many other texts.
A full mathematical analysis of amplitude modulation can be found elsewhere. Generally, the explanation of modulation given in popularized books is very oversimplfied. It is not really very intuitive.

Indeed, it's not. I had to look at a number of references to find all the information that I was looking for. In the end, it seems that both points are correct in the proper context.

Thanks for the comments.

Here's another one, from W8JI, who has been designing amplifiers for longer
than I have been a ham (and knows how to use lab equipment).

http://www.w8ji.com/cb_amplifiers_convert_ham.htm

"Pure 100% linear undistorted sine wave amplitude modulation has the following
power relationships:

Carrier power is 25% of peak envelope power, or if you prefer peak envelope
power is 4 times carrier power. A 1000-watt carrier is 4000 watts PEP with
undistorted 100% sine wave modulation.

Average modulated power output is 150% of carrier power. This is because
average audio modulation power is 50% of carrier power. A 1000-watt carrier is
1500 watts average power when 100% modulated with an undistorted sine wave.

RMS RF antenna current is 1.225 times unmodulated RF carrier current. A
1000-watt transmitter into a 50-ohm load is about 4.5 amperes unmodulated
carrier and 5.5 amperes load current when 100% modulated.

Peak RF output voltage when modulated is 2 times unmodulated carrier voltage. A
1000-watt carrier into 50 ohms is about 326 volts peak voltage and 652 volts
peak when 100% modulated."

Like I said, BOTH sets of numbers are correct IN THE PROPER CONTEXT. People
need to accept that and move on.

Paul,
Besides checking the resistors that Garey suggested, please also check R38. Your meter might be giving you the wrong information in regards to your bias and output current. You also indicated that you had only performed the procedures on page 37-38. You also need to do your Carrier Osc., Filter match & Balanced modulator, and Neutralization procedures. So if you have not done procedures from page 37- 40, please do so. They all have an effect on power output, some more than others.

Good luck.
Mark

Paul, I ran across a similar problem while renovating a friend's T4X-B. In his case, the cathode current sense resistor R36 (2.7 Ohms) had increased in value to about 8.3 Ohms, which meant the indicated cathode current was about 3 times greater than the actual cathode current. Replacing the resistor with the correct value got the meter to read correctly and tuning up to the correct current now resulted in full power output. Check R38 with a good DVM and be sure to verify your meter's "short circuit" resistance. It's not unusual to have several hundred milliOhms of resistance in the test leads. When reading these low value resistors, this must be taken into account.

Good luck,
Jim

Tim -

There is a complete voltage chart for ALL tubes in the manual. If you don't have a manual, _GET
ONE_. A tube type transmitter is NOT a VCR.

Improper operation can destroy all or part of the transmitter, cause a fire, etc., etc. Nothing good.

Voltages are approximate since in some cases power supplies are unloaded.

V5, Same for V6 except Pin 5 ~13 VAC, Pin 4 ~ 7VAC

Pin 1 ~260 VDC

2 ~ -62 VDC

3 ~ 85 VDC

4 ~ 0 VDC

5 ~ 7 VAC

6 ~ -62 VDC

7 ~260 VDC

8 0 VDC

9 0 VDC

Plate Cap. ~ 700 VDC

Happy Thanksgiving!!

Hi Mr. Barrell,

Thanks for the reply.
I have a manual, shows only transmit voltages, I should have shared what I am trying to accomplish here.
According to my meter I am registering cathode current even in receive, turning the bias pot in receive will indicate change in the meter. Power supply has been reworked, bias controls current for idle current and when in receive current looks to be present. What does cut off the pa in receive? I am about to check plate current to see if maybe the meter circuit is wrong. Can Cathode current be sensed from the other tubes connected in circuit? It has been probably 20 years since I have been inside a VCR. :)
P.S. I also have your CD.

Thanks for listening,

Tim Stotenburg

when checking low value resistors I prefer the simpson 260 over an auto ranging or switched DVM . I havo one of each of the dvm's and neither have a metre zero adjustment . with the 260 you can set the metre to zero before measuring the resistor and that compensates for any resistance in the leads .

In his case, the cathode current sense resistor R36 (2.7 Ohms) had increased in value to about 8.3 Ohms, which meant the indicated cathode current was about 3 times greater than the actual cathode current. Replacing the resistor with the correct value got the meter to read correctly and tuning up to the correct current now resulted in full power output. Check R38 with a good DVM and be sure to verify your meter's "short circuit" resistance. It's not unusual to have several hundred milliOhms of resistance in the test leads. When reading these low value resistors, this must be taken into account.

>when checking low value resistors I prefer the simpson 260 over an auto ranging or switched DVM . I havo one of each of the dvm's and neither have a metre zero adjustment . with the 260 you can set the metre to zero before measuring the resistor and that compensates for any resistance in the leads .

Some of the Fluke models (my 8050A, for one) have a "relative" mode that will compensate for lead resistance. There are probably other higher-end brands that have similar features. You probably won't find them at Harbor Freight.... :)

6105. R-7: nonworking AUX bands

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-27 15:52:29 UTC
From: Jose V. Gavila
Topic: 6105 Message: 6105

Hi all,

I am working on a R-7 which has a weird problem: all bands, in NORM position, work fine. But then, in AUX PROGRAM positions, they mainly refuse to work (from time to time, some of them work for a while). Thinking about faulty contacts I have removed, resoldered and reseated AUX7, DIGITAL CONTROL and DR7 boards but problem persists. BTW, SETBAND LED behaves correctly.

Is there any typical component fault which could cause this?

Thanks!

JOSE

Jose -

Sorry, I was looking at TR-7. The R-7 is a little different. Q201 controls NORM / AUX switching
via the PROM. I have also seen instances where the PROM outputs would break down, shorting the
output pin.

Hi Jose,

In addition to Garey's tips, don't overlook the obvious. I have been troubled lately by dirty contacts of the AUX switch in my TR-7. All positions except NORM are very intermittent. It will get a good cleaning when I find some bench time for that radio.

OK, thanks for the hint!

While I was watching the F-1 race ;-), the R-7 has been left in AUX position... and it is a thermal-related problem, as after about 15 minutes, all AUX bands have started to work fine. And they keep working!

Another info: I have available two AUX-7 cards and with both failure was present when cold. So I would say the problem is on the DIGITAL CONTROL board, and probably the PROM, right?

It is not easy to cool it directly to check it, I am afraid.

Is that PROM available as an aftermarket / spare part?

Regards,

JOSE

Hi again,

Checking the schematics I would say that a faulty PROM would also
generate faulty decoding when using the NORM position... so perhaps
it is a matter of the switching, as you suggest (Q201 or whatever drives it)

I will look for that possibility. Perhaps a 2N3904 is all what is needed ;-)!

Regards,

JOSE

Jose -

Don't overlook Q201... It wouldn't be the first plastic case transistor of that era to get 'flaky'.

Would be easy to get to with an extender board set. If you don't have one, an excellent after-market set is available from W7AVK for about half or less than the Drake sets go for. <http://www.wb4hfn.com/Services/W7AVK/tr7ext2.htm>

Cold spray!! :-)

The PROM is 82S123, a generic, fusible, easily programmed. American Microsemiconductor has them for
$20. Possibly others. I've had good luck with AMS, no minimum and reasonable shipping. Someone
was talking about replicating them some time ago, but don't think I have ever seen them. It IS a
different program than the TR-7 PROM.

The ones I have seen were blown such that an output would be 'open' on 'A' and shorted on 'B'.
Usually on more than one output, indicating perhaps some sort of contamination or 'whisker' growth?

Hopefully it's just a contaminated 2N3904!!

6114. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-27 20:46:46 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 6114

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

6115. Help... broken wire on R4B re-cap project

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-28 03:48:55 UTC
From: ve3tdn
Topic: 6115 Message: 6115

Ok, so I've got a minor problem on my R4B recapping project. Last night when I left things, everything looked normal. Tonight when I went back to work, I realized I had a single white/brown wire not connected to anything... broken solder joint. I can't find a likely connection within the sweep of the wire.

Pics are located in my photo album "VE3TDN R4-B Rebuild"

The other end connects to the tuning board. Tracing the schematics aren't helping me... I'm too used to newer style schematics where wire colours are listed.

Can anyone point me in the right direction so I can get this buttoned back up?

Thanks,
Doug

Doug -

IF the brown wire going to the Calibrator board is connected to the terminal at one end of the 180
ohm resistor, the other end connects to the 11V terminal in the center at the top of the power
supply board (the one with the 150 ohm 2W resistor in your first photo).

You should have had my CD! :-)

No luck so far... I replaced the 2N3904 with a new unit and it keeps doing the same: works OK after about 15 minutes being powered but, when cold, it fails to work but only in AUX band positions. I will continue checking things...

BTW, I have a TR-7 extender set but I had forgotten about it :-O!. So, yes, it seems a good moment to use it.

Regards,

JOSE

OK. Well, it never hurts to try! :-) Sounds like time for some cold spray on U201 and perhaps
some PC board traces. Sometimes traces develop micro-cracks that are temperature sensitive. A VERY
bright light behind the board will sometimes spot them.

Yes, it fails if I give it a shot of cold spray!. It is in a socket,
so I will carefully clean it and, if in doubt, will replace socket
with a new one.

In case U201 is faulty, has someone successfully programmed a replacement?

6121. New to this group, but not to Drake.

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-28 19:35:58 UTC
From: LonnieW
Topic: 6121 Message: 6121

Hello, I am N9IUI, Lonnie, and I live in Indianapolis, Indiana.
I got my first Drake, a TR4c, in about 1989 or 1990; my first HF rig.
I had a ball on 10 meters that cycle and fell in love with that old Drake. Luckily I still have him and he works fine.

I recently "won" an eBay auction for an MN-4 tuner which I had wanted for quite some time. I was suspicious because it was listed under CB Radio and not Ham Radio. The seller also stated that the "unit powered up, but we can't test further than that". I thought he must have mixed it up with something else so I took a chance, bid, and got it for a pretty good price.

I just received it today and I can't describe what I felt when I unpacked it and saw a power cord, fuse holder, and on-off switch on the back!

Who ever had this poor little MN-4 had "built" a power supply into it. It was ugly, I'm here to tell you.

I yanked all the extra stuff out and am hoping that the tuner part will still work. I'll find out tonight when I get home with it. Now I have three extra large holes and 4 or 5 extra screw holes in the back panel.

I have been unable to find a clean sharp photo of the inside of an MN-4 to compare. Does anyone have one they could post or email me? That would help in restoring this poor little thing to the way he was meant to be.

I'm just thankful the idiot only put one extra hole in the front panel, and it is small!

Lonnie -

Just a guess, but that may all have been for a peak reading circuit, which can be quite handy! So
don't throw it all away yet. :-)

See attached photos.

I don't think so Garey. It wasn't attached to the tuner or meter in any way. It looks like he just used the MN-4 as a case to hold the ugliest power supply in the world!

6126. Re: [DrakeRadio] R-7: nonworking AUX bands

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-29 18:42:30 UTC
From: Jose V. Gavila
Topic: 6105 Message: 6126

Hi all,

I have some advances on this!

Looking at the DIGITAL CONTROL board schematics I found that on any AUX PROGRAM position, the output of the PROM should be high impedance so it could be removed and receiver should continue to work. So I guessed that, if the PROM was bad, it could leave some output wrong when not selected. So I got it out (it is socketed) and the problem got worse!. Now, even when hot, AUX bands didn't work... back to think!

So, what was happening?. A couple of the PROM outputs were always zero in the programmed AUX bands but there was an slightly over zero (0.2-0.5V) voltage on the DR7 U9005 and U9006 chips (both MC15510B) and that voltage generated a wrong high output. Curiously enough, that happened only on one of the four input pins each MC15510B has (pin 3). So shen you put the PROM and it gets warm, that voltage goes a bit lower and then output follows input as it should.

So I did an old trick: put a soft pull-down (10k) on the problematic inputs. And, yes, it did the trick!. Now input is at about 0.05V when low and close to 4V when high (in my case, only on NORMAL bands) and output follows input.

Then I found an unrelated (well, I don't think so...) fault: UP and DOWN, when in NORMAL position, don't work always. Sometimes UP goes DOWN, DOWN generates more than one step and so on. I am studying the schematic as, guess what?... both MC15510B are part of the UP/DOWN system... so thay are suspicious. Or something around them.

The plot thickens...

Regards,

JOSE

Hi all,

It is FIXED!!!

I have found the reason for the faulty UP / DOWN function: one of the counters (U9006, an MC14510B) had a faulty input pin, which was polarizing the UP/DOWN pin (pin 10) with a weird 3.9V voltage. Once I have isolated the fault, I have replaced it (using a socket just in case it breaks again in 30 years ;-)) with a CD4510BE and voila!, UP/DOWN is working!

I have not replaced the other identical unit, U9005, as it seems to work OK. But I have needed to keep the pull-down resistors I commented on last message to get them working right, so I guess there is some problem in the MC14510B lot used in this rig (datecode 8029). And the DR-7 has no less than 6 units!. I hope they don't all fail in the close future, hi!

Thanks and best regards,

JOSE

6130. Re: Help... broken wire on R4B re-cap project

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-11-30 01:18:12 UTC
From: ve3tdn
Topic: 6115 Message: 6130

Garey,

Yes, the white/brown wire is going to the Calibrator board, at the end of the 180ohm resistor. I found the spot on the power supply board where I thought the wire broke off of, but wasn't 100% sure... there is only a tiny indent in the existing solder that the wire was originally nested in.

I guess I should have taken more pictures... and I didn't know there was a CD available.

Thanks for the pointers,

Doug.

Hi Frank,

Thanks for writing. The offers and inquiries have been few. Seems the TR-7s are not in demand now.
I have put it back in service and will keep it unless a local deal comes along.

73,
Ed

Congrats, Jose. I've seen strange stuff like that with CMOS before, not always easy to track down.

I have 2 TR-6's. I would love to buy an RV-6 (at least one) if anyone has one they would consider selling. I figure if I keep asking at least once a year, maybe someday I'll get lucky. Jim - WB6TNF

6135. I think I may have had a fatal failure

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-01 04:55:52 UTC
From: Dan Galligan
Topic: 6135 Message: 6135

I had mentioned a couple of weeks ago, that I had a blind friend, whom I would be helping sell some radios. He HAD a 2B and a 2A-Q Multiplier, which he got sold on his own. There was a mostly very nice condition Drake R4C, which he and a friend had briefly began to bring up on a variac, but it blew the fuse, when they plugged in the headphones (they didn't have a speaker with an RCA plug). Obviously, they stopped at that point. I went up to his home Monday night and picked up a BUNCH of old stuff, some of it NOS in boxes, much of it Boat-anchor-ish, the smallest radio, being a Heath HW-8, and the newest, being a nice shape FT901DM, including the R4C, and what appears to be a very nicely built, homebrew, 500 watt CW transmitter.
I brought it all to my house, and started getting it all un-dusty, and ready to check out. I connected a 4 ohm speaker, plugged the R4C into my variac, and brought it up to 20, then 50 then 70, then 100 volts, moving slowly between each step, and letting it sit for several minutes at each of those voltages. there was a 60hz buzz, from the speaker, the entire time. When it looked like all was going pretty well, other than the 60hz hum, and I had gotten to 100VAC, I stepped out of the room, for some water. When I stepped back in the room, (about 5 minutes later) it was smoking, from the right rear, so I immediately unplugged it from my variac. The transformer inside, continued smoking, long enough, that I was beginning to worry there was an actual fire, so I checked closely, and had none. I let it sit, rest and cool, for some time, and more than a half hour later, I removed the top cover, and the transformer was still HOT to the touch. I looked closely in there, and did not see anything, other than the forward, left corner, of the transformer, which had melted paint.
NOW, my question. Can any of you, far more knowledgeable folks, point me towards where to look for the root cause of the problem? A compounding factor, was too heavy of a fuse. Apparently, when it blew the fuse for them, someone replaced it with an AGC30, which I believe is FAR too big, for a receiver. I wish I had noticed that, before I started to apply voltage. I did look, but I saw a fuse that didn't appear blown, and it never crossed my mind to check the amperage rating.
Now, based on my descriptions, considering I am selling the radio for a blind friend, would it be best to make it a project rig, or sell as a swap meet/tech special? I've already told him we likely need to just get rid of it, but there is a lot of it, that still looks to be very nice, so I hate the idea of it being parted out. It has the NB 4, the CW .25 filter and the CW 1.5 filter, as well as being very clean internally and externally, with no signs of abuse, the only anomaly I found, visually, is the band switch has the wrong knob. Otherwise, no signs of anything to lead me to believe we would find any issues, other than old capacitors.
If I were to turn it into a project, this would be my first radio project, since the 1970's, getting a Viking II back on the air, so I will likely be asking a bunch of questions, if it becomes that.

Thanks for the help to come.

In my opinion, the first clue to a pending disaster was the 60 cycle hum in the speaker...indicating a faulty filter capacitor or multi-section filter capacitor in the power supply. If one happens to short, it throws a tremendous load on the transformer and unless present to disconnect at the first hint of foul smell, or smoke, I suspect the transformer is toast. This greatly diminishes the value of the transmitter or transceiver. Fiable, but could be pricey...a lot more expensive than replacing filter capacitors at the very beginning.

Subject: [DrakeRadio] I think I may have had a fatal failure

I had mentioned a couple of weeks ago, that I had a blind friend, whom I would be helping sell some radios. He HAD a 2B and a 2A-Q Multiplier, which he got sold on his own. There was a mostly very nice condition Drake R4C, which he and a friend had briefly began to bring up on a variac, but it blew the fuse, when they plugged in the headphones (they didn't have a speaker with an RCA plug). Obviously, they stopped at that point. I went up to his home Monday night and picked up a BUNCH of old stuff, some of it NOS in boxes, much of it Boat-anchor-ish, the smallest radio, being a Heath HW-8, and the newest, being a nice shape FT901DM, including the R4C, and what appears to be a very nicely built, homebrew, 500 watt CW transmitter.
I brought it all to my house, and started getting it all un-dusty, and ready to check out. I connected a 4 ohm speaker, plugged the R4C into my variac, and brought it up to 20, then 50 then 70, then 100 volts, moving slowly between each step, and letting it sit for several minutes at each of those voltages. there was a 60hz buzz, from the speaker, the entire time. When it looked like all was going pretty well, other than the 60hz hum, and I had gotten to 100VAC, I stepped out of the room, for some water. When I stepped back in the room, (about 5 minutes later) it was smoking, from the right rear, so I immediately unplugged it from my variac. The transformer inside, continued smoking, long enough, that I was beginning to worry there was an actual fire, so I checked closely, and had none. I let it sit, rest and cool, for some time, and more than a half hour later, I removed the top cover, and the transformer was still HOT to the touch. I looked closely in there, and did not see anything, other than the forward, left corner, of the transformer, which had melted paint.
NOW, my question. Can any of you, far more knowledgeable folks, point me towards where to look for the root cause of the problem? A compounding factor, was too heavy of a fuse. Apparently, when it blew the fuse for them, someone replaced it with an AGC30, which I believe is FAR too big, for a receiver. I wish I had noticed that, before I started to apply voltage. I did look, but I saw a fuse that didn't appear blown, and it never crossed my mind to check the amperage rating.
Now, based on my descriptions, considering I am selling the radio for a blind friend, would

it be best to make it a project rig, or sell as a swap meet/tech special? I've already told him we likely need to just get rid of it, but there is a lot of it, that still looks to be very nice, so I hate the idea of it being parted out. It has the NB 4, the CW .25 filter and the CW 1.5 filter, as well as being very clean internally and externally, with no signs of abuse, the only anomaly I found, visually, is the band switch has the wrong knob. Otherwise, no signs of anything to lead me to believe we would find any issues, other than old capacitors.

You are aslking for a rare item. An RV-4C will work, but you have to allow for different dial markings. And would probably be a lot cheaper.

I agree with Bernie, the 60 cycle hum was a warning sign that you probably should have shut down to investigate. The transformer is probably toast if it got that hot. Even if it's not, it may only be a matter of time, as the internal insulation will be badly scorched. If the rig is in nice shape, hang onto it as-is. You should eventually be able to find a transformer out of a parts rig. The other option is to have the transformer re-wound, but that won't be cheap. Don't give up, I found a NOS transformer for my HyGain 3750, practically right under my nose as it were. I paid a good price for it, but it was cheaper than a rewind would have been.

This exposes two rules that many of us learn the hard way. ALWAYS check the fuse for proper size before powering up a "new" radio for the first time. If you find an oversize fuse, suspect a BAD reason for it to be there. Second rule (and one that some people disagree with) is NEVER leave a vintage radio powered up unattended. Period. It doesn't take long for a fault to destroy an unobtanium part, and if you're there, at least you have a chance to minimize the damage.

Yeah, I do see R4C's occasionally, at the local swap meets, or on QRZ/QTH, so maybe I ask my buddy, what he wants for it, in it's condition. With the filters and noise blanker, NOT being in my personal R4C, it might be worth grabbing it up, and using those options on my current R4C (though I still prefer my R4B)
Even though it is bad news, I appreciate it. It was pretty much what I expected.

Well the bulb issue is because I put a #47 in and it needs a #53, I've ordered the #53's. Still nothing from the VFO, and the resistor #R16 22K 2W, is that there for the TR-3? Not that I have a TR-3, but its a bit confusing the schematic shows the 22K 2W, and it's in the same place that you would add one if your using a TR-3. I'm confused.

Ted -

First question, is it an early or a late RV-4C. What power rated resistor is in place for R15.??

If R15 has gone way up in value, -OR- Q3 has shorted, it would explain your symptoms.

R16, 22k 2W has no special TR-3 function. The only 'mod' to use with a TR-3 is in the TR-3 the
jumper wire between pins 2 and 8 of the connector.

I have a TR-4 not C model, and the RV-4 is not a C model. The instructions, say for a TR-3 place a 22K 2W resistor from the orange wire to the pin 1 of the 0A2. The schematic shows this 22K 2W resistor going from the orange wire to a junction off 0A2. I see no transistors. The transistor must be in the VFO can.

In the schematic that matches the RV-4 there are 2 transistors listed Q1 & Q2 there is no Q3. R15 & R17 are within tolerance. R16 also measures good.

Ted -

OK. sorry, that's a REALLY early TR-4. It has the 0A2 VR tube in it. There is NO Q3!! :-)

I still don't know of an variation with the TR-3 except for the jumper wire IN the TR-3. No matter,
you're using a TR-4......

You should measure very close to +150 VDC on Pin 1 of V2, and very close to +10 VDC on the 'other'
end of R15. While you're in there, check the voltages on Pins 3 and 8 of V1. They should measure
about 4.2 on Pin 8 and 42 on Pin 3.

From: Garey Barrell
Topic: 6135 Message: 6151

I have no idea what it would take, as I never had enough to matter when that was my dummy load. I
DID work a half dozen stations while loaded into a light bulb... :-)

A guess would be about 20% over? Depends upon how long? 150% would probably take it out pretty quick.

When used as an equipment protector, it really doesn't matter what size bulb you use, as even a
completely shorted transformer would cause it to light to ONLY full brilliance. Normally you try
and use a bulb of approximately the power requirement of the unit under test. Most receivers work
fine with a 40W bulb.

I simply wanted to post here that I bought one of WA4NJY, Ed's, Drake microphones, and it arrived today, well packed and in great shape, just as he described. It was a deal I am very pleased with, and I wanted to let the group know that Ed is a great guy to deal with. Honest, thoughtful and considerate.
Thanks Ed, for being a "stand-up" kind of guy.

What I have found, pin 3 of tube V1 has no voltage, and checking the cable, that line is dead, must have a broken wire in it.

Ted -

OK. sorry, that's a REALLY early TR-4. It has the 0A2 VR tube in it. There is NO Q3!! :-)

I still don't know of an variation with the TR-3 except for the jumper wire IN the TR-3. No matter,

you're using a TR-4......

You should measure very close to +150 VDC on Pin 1 of V2, and very close to +10 VDC on the 'other'

end of R15. While you're in there, check the voltages on Pins 3 and 8 of V1. They should measure

about 4.2 on Pin 8 and 42 on Pin 3.

Replaced the broken wire, I had to piggy back it to the harness so it was the same length as the original. It's alive!!!

From: fred
Topic: 6135 Message: 6156

i have had better luck using a 25 watt bulb on the first test , it will light about 1/3 and slowly get brighter as the rectifier warms and the set starts taking current . the ecperiance I had using a 40 watt was that it would not light at all unless there was a heavy load . . used it to smoke test early 30's AC recceivers . you can change to a highrer wattage if needed. usually you won't need to .

From: kevin gray
Topic: 6157 Message: 6157

Hello I have a Drake MN 2700 that has a Blown 170 pF transmitting capacitor. This is one of the bank of capacitors located under the Reactive Variable Capacitor toward the back of the tuner. They are Rectangular 1¼ inch wide by 1 inch high and have small bolt holes for mounting

Thanks

Kevin

The frequency display went blank again and I do not feel like pulling the connectors and the DR-7 board again. This one has the NB-7 noise blanker and filters SL6000, SL2300, SL1800 and the 300Hz CW filter.

Anyone care to make an offer for the transceiver plus whatever exact shipping will be? Also have the power supply. Hate the thought of packing this heavy weight but it needs a new home.

Email me if interested

6162. Drake 2-B and 2-C Differences

Hi Fellas from Pensacola FL.

Never owning a Drake 2-B before but a very good condition 2-C in my radio shack for many years, I've often wondered what the electrical differences were between the two receivers.

Of note: I have a 2-BQ matched up to my 2-C and find that the 2-CQ is a carbon copy of the 2-BQ electrically.

tnx es 73. Merry Christmas

Robert W4RL

Hi Robert -

The biggest operational difference is that the 'C' does NOT have Passband Tuning. It also is solid
state from the Last IF on. The BAND Oscillator, all the AVC, Detector and audio is silicon. This
makes the 'C' a serious downgrade from the 'B', at least in my opinion. The dial mechanism is a
little nicer, but other than that, no contest!

Yes, the 2-AQ, 2-BQ and 2-CQ are essentially identical electrically, and not far from the old
Heathkit QF-1... :-)

The best way to avoid this problem is not to keep contact information on web based email programs or servers. Keep them on your resident email program then copy and paste into your messages. It is a bit of a hassle but it saves you and all of us from this type of thing.

Subject: [DrakeRadio] hijacked email do not open any links or attachments from me

On Friday, a business pc hijacked my email account and password and sent a link for a pharmacy that was bogus with hidden exploits to everyone in my mail directory.

One of my friends noticed that he received an email from another source containing the same infected link. If you opened the link, here are some online virus scanners that will scan your pc. If you did NOT open the link, you are safe if you delete the email.

If you wish to download a good anti-malware and anti-virus app, you can download and run malwarebytes below.

Sorry for the inconvenience. If your email gets hijacked, like mine did, you must change your email account password to stop the bot from emailing your directory contact lists.

regards... Al.

Unfortunately, this is not strictely a webmail problem. Your advice is good, but these cretins can also harvest information and spoof email addresses from M$ Outlook directly if the host computer becomes infected. The best solution is to not use webmail OR M$ Outhouse. There are plenty of alternative email clients out there that are not as vulnerable.Thunderbird and the Seamonkey suite are two that come ti mind.

Larry -

Gold mine!! Hopefully 'Station #1' is just a physical examination! :-)

Sure looks like a final Alignment and Test Procedure to me. Should also apply to just about all the
TR-4C models too, excepting CW and CwRIT features.

I especially like things like Station #3, Section 6!

Thanks for posting...

The gentleman I got my TR 4 from was a physicist at Wright Patterson AFB here in Dayton, Ohio. He had the distinction on being on the team that scoured Germany for high technology after WW II. He once told me that if he took anything into work at Wright Labs, he couldn't bring it back out. Anyway, I believe he knew people at Drake.

Glad the group might find this of use; I thought the handwritten notes would be of interest too. They appear to add the NB in parts.

Yes, there is a switch on the rear labeled "norm/ext" and an RCA jack just below that switch that you can use to access the counter. I don't remember the limitations (it's in the manual that I don't have handy), but be careful how much you put into that jack.

Yes Garey, rf tune peaks on 80M where it should but it is a very little peak. No peak on 160M. No, gear is not new to me, but I have never used it on the low bands before. If I switch from separate to rcvr, I get no peak at all. Switching to xmit, I get a little peak like separate.

Jeff Covelli went through the tx and rx a couple of years ago and said all was working well when he was finished.

OK.. Almost certainly a bandswitch problem. Possibly just exercising
the switch through those positions. If not perhaps a judicious
application of DeoxIT to the appropriate contacts. Don't forget the
ones over by the BAND oscillator (where the crystals are.)

Remember that you need an additional optional crystal for 160M, and have
to select one of the auxiliary NORMAL positions where that crystal is
installed.

Ok on the 160M Garey. I had forgotten that. Just haven't used the Drakes enough lately.

I did clean the bandswitch with Deoxit and exercise it quite a bit. No joy.
Ordered replacement tubes, so I'll try some substitutions even though the ones in the tx check ok on my tv-7d/u tester.

6184. TR-7 display puzzlement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-09 20:15:36 UTC
From: Gary Woods
Topic: 6184 Message: 6184

Well, I figured out that reseating the upconverter board restored full power and Rx sensitivity, but now the display shows only a decimal point. The aftermarket display board is correctly snugly plugged in, the scan signals all look reasonable, and the protective circuit is not activated. What really, really dumb thing am I overlooking? I have good output and Rx now...
TIA,

Wayne -

OK. It's not going to be a tube.

Check the manual for the alignment instructions. Tune up in TUNE
position. Keep the resonant plate current under 200 mA and monitor the
output power. The four trimmers along the left side of the transmitter
that are marked 3.5 MHz can be tweaked. Be careful to use an insulated
tool to adjust them, as shorting one to the chassis even momentarily can
destroy a resistor in the transmitter. Note their position, turn a
quarter turn and see what happens. If no change, return it to it's
original position and try the next one. The two trimmers nearest the
rear of the transmitter are the Driver Grid and Plate adjustments. The
other two are for the Premixer and less likely to be the problem here.

What does the display look like when the switch in the rear is in Frequency Counter mode?

The same, unfortunately... and when I put 10MHz TTL-level in the external
input and select Frequency Counter mode, nothing different happens.

Well, I figured out that reseating the upconverter board restored full
power and Rx sensitivity, but now the display shows only a decimal point.
The aftermarket display board is correctly snugly plugged in, the scan
signals all look reasonable, and the protective circuit is not activated.
What really, really dumb thing am I overlooking? I have good output and Rx
now...
TIA,

6189. R-4B AGC (AVC) on AM

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-10 09:21:26 UTC
From: mike
Topic: 6189 Message: 6189

I'm hoping someone can help me... as you all know, the R-4B (& most other Drakes) have Fast & Slow AGC options for SSB, but AM is fixed at Slow.

I want to change mine to be fixed at Fast instead. I've studied the schematic & finally deciphered the switch wafer positions (I think) but I'm still not sure what needs to be changed to alter the AM setting without upsetting the SSB positions.

Can't be hard, surely?

Has anyone done this mod already?

73,
Mike

Mike -

I maybe missing something, I don't have a receiver with me to look at,
but looking at the schematic it looks like the way to do it is to lift
R81. I'm not sure, it's hard to tell just what the switch wiper
blades will cover.

I had checked that, and even unplugged the connector to it (it just grounds
the load/update strobe) to no avail. BUT: the strobe is missing, and
waveforms in the vicinity look weird, so thanks for pointing out the area.
Will dig deeper after doing seasonal things like stringing lights, etc.

Hi Garey, I was hoping you'd respond... much appreciated.

I've pored over the schematic &, as you say, it's pretty hard to see just what the switch is doing.

I *think* this is what's happening:

Fast SSB - the blade is inbetween ALL the contacts, i.e. NO connections.
Slow SSB - R81 connected to R143 & C109
AM - Blade connecting to Q4 collector, but to me it looks like there is no longer a blade connection to R143, but I think there must be, to keep the 0.22uF in circuit & give the slow response.

If I'm right, then the only way I can see to speed up the AM AGC (& not alter the SSB AGC) is to insert a largish R in the top switch contact (AM position) to reduce the effect of R143/C100.

Certainly an easier way to do it is to reduce C109, as I don't use the SSB Slow AGC either, but I'd rather leave it as it is.

When I eventually open up the set then I expect it will become clearer, but there's too much to move/unplug at the moment. :)

73,
Mike

No, both the SLOW and the AM positions connect R81 to R143. The blades
are 'double wide' on both sides. So lifting R81 will convert SLOW and
AM both to FAST. To get SLOW on CW and FAST on AM you'd have to remove
half of the wiper blade on either side! Not an easy task. I suppose it
could be done with a Dremel, but I'd want a spare wafer!! :-)

I'm getting a headache!

I've decided to stop thinking about it until I can open up the set & find out precisely what goes on at each switch position.

I'll report back then.

Garey,
Whilst you are going about your normal "good guy" helping, and the topic is AM on the R-4B, would you mind sharing with me and others if they are interested what you would think to be an "easy" way to widen the 4.8 filter position a bit?? 4.8kc is just a bit "pinched" and 6 to 8kc with that nice, Drake tube audio would really sound great!!

I realize that I should know at least a "crude" way, but your solutions are always easier to implement and much more "elegant", as my British friends say, hi.

Hi Don -

About the only way would be to bypass the Passband Tuner, (Plate of V4 to the Grid of V5,) with a 0.001 or 0.01. It's possible that you could leave the PB tuner in place, just 'go around' it, but it might be necessary to lift the output from the Grid of V5. This would set the IF at 8 kHz, the b/w of the four pole 'roofing' filter (T6). You'd have to look, but it might be possible to rig a microswitch to add the coupling cap when you turn the PB tuner knob to 6 o'clock. You might also end up with some 'blow-by' of out of passband signals depending upon lead length, switch capacity, etc. Certainly not a 'plug-and-play' mod, but probably could be done.

From: Don Cunningham
Topic: 6198 Message: 6198

Thanks, Garey. I was afraid widening AM on the R-4B wasn't as easy as "change Cxx to .0xx from .0x". What you describe is too much of a "mod" to the rig for my liking, but what I expected. I have other rigs that I can use on AM, so I won't harm a good R-4B to do it and will just use the R-4B as it was designed. It was just a thought.

For those inclined to "tinker" and "restore" Drake equipment, stay tuned after the first of the year. I will be offering some gear for sale, both 4 and 7 line, to the Drake lists first in differing degrees of needing TLC. I don't know exactly what or how many yet, but I need to DOWNSIZE greatly and have decided I won't try to fix them all then sell them, so you can save some funds and have fun at the same time!!! Some will be in perfect working condition. This is NOT a "fire sale" however, so don't expect them to be giveaways. I DO tell what I know about each one, and will provide pictures to serious requesters.

More to follow, but after the holidays.
73,
Don, WB5HAK

With most things, step one of troubleshooting is "check the power
supplies."
In a TR-7 that matters, but "clean the connectors" seems to take care of
most strangeness.

6205. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-11 20:15:35 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 6205

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

6206. L-4B Input Coil Adjustment

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-12 11:03:43 UTC
From: MarkB
Topic: 6206 Message: 6206

Hi Group
I Think I need to do an input Coil Adjustment on my L-4B
I have checked the adjustment as per the the Instruction Manual
I Have reading of:
10m 1.9-1
15m 1.2-1
20m 1.8-1
40m 1.3-1
80m 1.5-1
How low of a SWR can should I have? or is this OK
Thanks Mark
VK2MTB

From: Donnie
Topic: 6206 Message: 6207

Mark:
One thing I would try first. I would try a different cable length between
the exciter and the input to the amp to see if you get different readings.

6208. TR4C AF/RF control with on/off switch

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-12 19:44:04 UTC
From: lonelyone_64109
Topic: 6208 Message: 6208

Anyone know of where I can find a replacement AF/RF control? The volume control shaft in my rig has become loose enough to where the volume stays loud even with the pot fully CCW. You can grasp the knob and feel the shaft wiggle just enough to cause the loud volume issue. Headphones that have a volume control in them help but the volume is either too loud or too soft. Alternately if someone has dismantled the pot and "tightened" it up that would be another possibility if necessary.I would prefer a replacement control if at all possible.

I am also contemplating building the audio limiter circuit in the Feb 2011 QST.Seems like this would be a possible "fix" until I can repair/replace the control.Any comments on this?

I love using the rig and still get many good reports with it. Its also sentimental to me as it was my OM and my first phone rig when we made General in 1972.

I rebuilt mine, I bought some similar pots awhile back, only the RF gain pot is the same, but taking them apart I transferred the old resistance board from the old to the new, then reassembled. I have done this several times, on Swan and Heathkit rigs.

I have contemplated rebuilding mine and may end up doing that.However, I found the CTS website and they make a dual pot and can have the on/off switch on it so that is another possibility.Don't know what one would cost but will be checking Mouser, Newark, Digi-key, and other distributors for one.Thanks for you input!!!

6211. R-4A RCVR SENS adjust problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-13 14:56:19 UTC
From: Gary
Topic: 6211 Message: 6211

Hi guys,
Even though it seems to be working fine, I decided to touch up my early R-4A a little. Think I found a problem...
As best as I can see in the manual, when you adjust the RCVR SENS, the AVC should be on SLOW/SSB.??
In that position, I can not get the -1.35V, only -0.4-0.6V (about).
Tried both DVM and old VTVM, no difference.
I did find that if I set the AVC to OFF, it adjusts just fine, -1.35V no problem.
Searching the past posts, I see a gassy 12BZ6 might be involved. And, pulling V1 does let me get -1.35V in SLOW AVC. Pulling the other AVC controlled tubes doesn't fix it like V1 does.
I don't have access to a tube tester or spare tubes.. what is the next step?
TIA,
73,
Gary

Gary -

Get some spare tubes, AND verify that they're good in a working receiver if possible. Especially 12BA6 (several) and 12BZ6. Tube tester is next to useless. You might want to consider changing V1 over to the 6 volt bus and use a 6BZ6. The 12BZ6 was fairly rare when the receivers were built, and haven't gotten any cheaper!

Try to set the voltage when the receiver is first turned on from cold. Gassy or Grid Emission tubes 'usually' aren't too bad 'cold', and get worse over 10-30 minutes.

Can you set the voltage in FAST? If you can, might check C109 (leaky.)

What s/n?

Unless someone says that the readings you got are
normal the only thing to do is to replace the tube. A few
tube testers will check for gas but most do not and in any
case the best test for many tube-caused problems is to
replace the tube. I suggest getting more than one
replacement because even unused tubes can have problems.
As a general rule while tube testers are useful even
the best ones are not the court of last resort, tubes often
test good but won't work in a particular application.

Thanks guys.

This is an early 13 tube A, serial 8740, Very Good to Excellent
condition I think.
I do see on ebay the 6bz6 is a lot more available.. Any prefered
vendor or brand??

FAST works just like SLOW, ie: doesn't adjust properly
(BUT remember, the receiver works fine as far as I can tell,
maybe not the really right gain distribution or ?? but...)
I was using it to listen to the 10meter contest this weekend
and was amazed that it could copy weak DX in QRM better than my
Kenwood TS-440s.. and I always thought my Drakes performance kind
of dropped off at 10meters.

Any chance the 12AV6 is bad?

Are there symptoms to failing 12BA6's? I didn't think 50KHz
would stress them too much ;-)

Question: Is the R-4/R-4A more problematic in the AVC area?
I have been toying with the idea of just modifying it to the
R-4B circuit, doesn't look that hard.. I know, I know, it will
make my $200 receiver into a $100 receiver but I have had it since
1980 and don't plan to ever get rid of it...

73,
Gary

Gary -

I assume that you mean 3740 for the s/n. The 11 Tube version started at 4054.

Generally prefer Sylvania, RCA or GE, although many other Brands were actually made by these companies.

Inability to reach 1.35V in FAST usually means that C109 is ok, don't see many bad ones though.

All you have to do is look at the AVC specification (3 dB change in output for 60 dB change in input) to see that there is LOTS of excess gain. The only way to determine a properly operating receiver is by watching the S-Meter.

It's possible that the 12AV6 is weak. Another reason to have at least one set of spare, KNOWN GOOD tubes on hand.

The 12BA6 is particularly susceptible to gas or grid emission. Most common symptom is a 'drifting' S-Meter ZERO, i.e., ZERO at turn on and meter drifts up, or down for the first 30 minutes to an hour.

The AVC in the R-4B is no better than that in the R-4A, with the exception of possible tube failure. Transistors also fail, particularly Q4, which is operating beyond it's rated voltage. Fortunately, transistors are specified as 'minimum' or 'maximum' safe operation, and most perform better than specified.

6217. "New" TR7 Refurb Progressing...

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-14 02:03:59 UTC
From: dcolb121
Topic: 6217 Message: 6217

Bought one of these beauties over at ebay.

Didn't transmit, even though the seller said all worked good (a non ham, of course). I found a bad solder joint on the low pass board, now she's transmitting fine. 110 watts on 10 meters.

Added internal preamp using the "store" button to change gain, new yellow display and replaced dial lights with white leds (dial and meter are now BLUE!) along with cleaning the PTO ball bearing raceway. Tunes nice and smooth now.

Had the old "sticky paint case". Refinished with a nice textured black.

Right now she's my main rig with a new Yaesu FT450D sitting on top that hardly gets used.

Having trouble finding mic for her though. I was able to find an old Uniden four prong mic from a dead CB that fit.

Got it all rewired to work with the rig, but the problem I'm having is that xmit audio is very bassy. Any thoughts on how to fix this? It's an unamplified mic.

Don WA7OCZ

Get a better mic?

Seriously, this radio deserves much better than an old CB mic. And it's not hard to find a good mic, online or at hamfests. For casual QSOing and rag-chewing, any of the dynamic Shure 444 variants is a good choice. For DXing and contesting, look for a decent high-impedance ceramic mic; Turner 254HC, EV 729, and modified D-104 are some that I have tried with excellent reports. A Turner +2 with the preamp removed would essentially be a 254HC. The Turner +3, with or without the preamp, would also be a good choice (the preamp isn't needed with the TR-7 for gain, but it has some audio compression that actually works). The dynamic Drake 7077 (really a rebadged Astatic) was the Drake accessory mic for the TR-7, but they are somewhat hard to find and expensive when you do find one. The one that I have didn't stand up to a Shure 444 for sound quality in the dynamic class.

Other readers will have other recommendations.

Also, be aware that most TR-7s have two input pins on the mic connector - one for low-imedance dynamic (like your CB mic), and also a high-level input for ceramic mics.

Thanks Garey.
OOPS, 3740, right you are! Drake's '3' sure does look like an
'8' when you look down over the back ;-)

I ordered some RCA(like my 12bz6) 6bz6's for the first step. Any
tips on wiring to 6V?
Looks like I should put it on the other side from the dial lights..

I don't think I have much drift of the meter.. maybe just a little.

I'll have to check FAST again, think it worked identical to SLOW.
C109 IS a big paper(?) unit. It looks like Drake changed it to a
smaller one with series resistor in the R-4B..?

Q4 seems to be really obsolete, I can't even find a datasheet.
Is there any available substitute? Drake used them "out of spec"?
Wow. Interesting. I still remember the one time I listened to an
R-4B. It was at the ham store when they just came out. I had
another R-4A at the time and I thought the B sounded really WORSE!
It was like the SLOW AVC wasn't really all that slow, like my dad's
75S-3B or there was some distortion or something. From what I read
now the R-4B is supposed to sound really good, like the R-4A.. maybe
that one was just a little too far out of spec!

73,
Gary

6220. MN-4 calibration?

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-14 15:05:08 UTC
From: LonnieW
Topic: 6220 Message: 6220

As I mentioned in a previous post, I got an MN-4 off that auction place and found that the previous owner had build a power supply into the tuner's case.
I ripped out that mess and am having trouble using the tuner.
I have a friend with the same tuner so he loaned me his to compare parts placement, leads, etc and my tuner seems to not have been harmed except for the small circuit board inside.
It looks like the tuning slug was ran all the way in with the brass part of the slug hanging off the end of the form.
Does anyone have instructions for calibrating this board back to where it belongs? Thanks!

Lonnie, N9IUI

Subject: [DrakeRadio] "New" TR7 Refurb Progressing...

Bought one of these beauties over at ebay.

Didn't transmit, even though the seller said all worked good (a non ham, of course). I found a bad solder joint on the low pass board, now she's transmitting fine. 110 watts on 10 meters.

Added internal preamp using the "store" button to change gain, new yellow display and replaced dial lights with white leds (dial and meter are now BLUE!) along with cleaning the PTO ball bearing raceway. Tunes nice and smooth now.

Had the old "sticky paint case". Refinished with a nice textured black.

Right now she's my main rig with a new Yaesu FT450D sitting on top that hardly gets used.

Having trouble finding mic for her though. I was able to find an old Uniden four prong mic from a dead CB that fit.

Got it all rewired to work with the rig, but the problem I'm having is that xmit audio is very bassy. Any thoughts on how to fix this? It's an unamplified mic.

Gary -

Yeah, they DO look a lot like an '8'!! :-)

OK, the 6BZ6 works fine, and as I'm sure you discovered is considerably cheaper than the 12. You
can pick up the 6V filament voltage on Pin 3 of V2. Check with DMM to ground, if 12V on Pin 3,
there will be 6V on Pin 4. It's been a LONG time since I have done one of these, and I really can't
see even on the CD. Going from memory (risky!) the filament wire comes from Pin 4 of V1 to a
terminal strip that is mounted on the shield plate between switch sections. SHOULD be a Wht/Grn
wire, but no guarantees. As I recall, you need to remove the wire from V1 from that terminal and
extend it to reach AROUND the chassis shield and down to Pin 3 of V2. Sorry I can't be more specific, but I don't have all my notes/references with me! You really don't want to put in a 'new'
wire as the wiring around V1 is VERY tight and just too many things to go wrong with a hot soldering
iron in there! :-) Also, be sure and 'dress' the new wire right against the chassis, and of course run it 'around' the end of the chassis shield, NOT 'over the top'!

The S-Meter drift will occur in the first 30 minutes or so. It's a progressive thing, so starts
with just a little and then gets annoying..... :-)

C109 is a 0.47 film cap. Orange Drop type, but with axial leads. Polyester, polystyrene, whatever
film. If the BIAS voltage doesn't change from FAST to SLOW, the cap is ok. I don't think I've
ever found a bad one at this position aside from a couple where a soldering iron got too close! The
'B' went to a 0.22 uF with 33k in series, resulting in essentially the same t/c.

Yes, Q4 is LONG obsolete. We went through this on one of the lists in the last year or so. The
problem is the Collector/Base breakdown voltage, so if one is working, it will 'probably' keep
working. Seems like we ended up with a 2N5550, but again going from memory!

6223. X-Lock/huff and puff

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-14 18:10:46 UTC
From: Paul Horvitz
Topic: 6223 Message: 6223

Thanks to all (with special mention to Garey) for the help you guys gave me with my TR7. It's been on the air on 160/80 and 40 SSB and CW for a couple months now. Working nice and reliably.

I'm wondering about the X-Lock for stopping it's drift up the band as the chassis warms up after transmitting for a bit. Same drift rate when running the RV7, so it's something in the mixing scheme on rig's chassis. The drifting is minor, about 100 cycles after 5 min of transmitting (NCS on a NTS net). I have a fan mounted on rear and within 7 or 8 min of no transmit the TR7 drifts back to starting freq.

Does anyone here have any experience using that X-Lock?
On the web site for cumbriadesigns it mentions they will have some more for sale this month.

I'm mainly wondering two things:
Will it address my drifting problem since it's not the PTO causing my TR7 to drift?,
is there another, better way to solve the drift?
Like tracking down caps and replacing them with silver mica's or mylar's or something?

Thanks,
Paul

CRT driver transistors have nice, high breakdown voltages. I ended up using one from a scrap high-end monitor circuit board in the ALC circuit of my 3750; the previous owner had replaced the original with an NTE sub that turned out to be a bad sub (nowhere near the correct ratings).

It's a pretty standard directional wattmeter circuit. The "slug" is a piston variable capacitor. You need a good 50-Ohm dummy load. The capacitor should be adjusted for minimum reflected power reading into the dummy load with carrier applied from your trasmitter. Do it on 10 meters, bring power up enough to get a reflected reading and adjust the capacitor for minimum. Increase power and repeat until you get the best null at maximum power. You can calibrate the power reading by adjusting the variable resistors to match a known accurate wattmeter connected in deries into the same dummy load. Reverse the connections to the tuner to calibrate reflected power.

If it won't calibrate, one or both of the detector diodes may be blown. You can find a manual with schematic on the WB4HFN web site.

Just a thought...
If it sounds pretty bassy on Rx as well with out using PBT, those voltage divider networks for the fixed passband tuning could be a bit out of adjustment. they are on the "Power Supply" board and there is one adjustment each for AM, RTTY, CW, LSB, USB. The main 10.000vdc adjust is also on that board (R2111). They were all out of whack with my TR7.

Actually I'm not sure if they affect transmit as well as receive, don't think they do. Perhaps someone on here more knowledgeable than I am can comment.

I use a 444 on my TR7 and get great audio reports, sometimes unsolicited ones!

Paul,
PBT is a receive function, not effecting transmit audio. The only way to change your audio (other than butchering the rig as advised on some sites) is to change the microphone to match your voice characteristics. I too get great reports using a NOS Shure 444D I happened to find on the internet for sale, but I also get great reports with an amplified D-104, with gain near off that came with one of my TR7's (sorry Jim), so the microphone needs to match your particular voice.

Otherwise, I have been successful on some rigs with one of the older equalizers made for radio use (by the W2xxx group, call slips my mind). HOWEVER, you can add some RF into the system easily using this outboard stuff. Bob Heil published a simple 2 band equalizer in one of the popular ham magazines when he first started that had a simple preamp and a couple of "bands" of equalization that might help.

I think Jim Shorney was right though, I would change the microphone. The caveat is that most microphones are being sold for a reason, and it's not always just "surplus to my needs", it may have "sounded like %$&* with my rig" or the element isn't very good. Some have had good luck with a cheap mic element from Mouser, others say it's junk, so it depends on the individual's voice characteristics. Is that why I have SO MANY microphones here, hi hi.

The fixed passband pots set the "default" passband for both TX and RX. PBT is an RX only adjustment, as already mentioned. You bring up a good point, Paul. The fixed passband adjustments are worth checking. If the DR-7 has ever been pulled for replacement of the PTO lamp, it's very likely that one or more of the pots was bumped without the op even noticing. The +10 should also be checked, but if it's real close, left alone or the S-Meter/AGC adjustment will also need to be done. Adjusting the pots can be done with a senitive frequency counter, or with the quick and easy method from Drake. It can be found on the Drakelist web site, and possibly WB4HFN as well.

February ,March and April 2010 issues of CQ-DL (Germany) contain three intersting articles by OM Paul, DK2QO, describing a significant modifications to TR7. He designed a new up-converter and second mixer board, which replace the original boards.Also, some changes to IF chain,PA and ALC have also been implemented.
This modification results in 10dB improvement of IP3 and intermodulation @ 2kHz by 20 dB.

6234. problem with bias on 40 meters cured

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-18 22:01:12 UTC
From: yash@aol.com
Topic: 6234 Message: 6234

Thanks every one for the help with no bias control on 40 meters problem. I did neutralize the finals, didn't change. I cleaned the driver tube pins,and socket, cleaned the surface between the socket finger ground and the tube cover and redid all the grounds connections for the board. Problem solved,all works well,proper bias and full out on all bands.

Now have a second problem,the audio both usb/lsb seems scratchy and tinny. I looked thru the article ,optimizing the sb/hw 100/101/102. they gave various resister and cap changes ,but There is no way to get into these boards while mounted on the chassis,and being so old,to easy to damage things bu pulling the boards. Is the component change the way to fix the audio or Iam I over looking something in the alignment maybe.
thanks again for the help

Dale -

I must have missed your original post on 40M BIAS? Could you describe the symptoms again please?

On your audio problem. The 4 Line has excellent audio, so something is wrong. Typically, audio is
'tinny' on one sideband and 'bassy' on the other as a result of incorrect Carrier Oscillator frequency.

If it really IS tinny on both, I'd suspect C138. Not a common failure, but a few DO get leaky.
When you get your CD, it's on Board 2, and not TOO difficult to replace.

6240. FS: Crystal Sockets

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-19 15:11:02 UTC
From: Bry Carling
Topic: 6240 Message: 6240

FOR SALE: Crystal Sockets

FT243 Crystal Sockets - 1/2" spacing X 0.094" diameter pins

Single FT243 Socket - two hole mount - classic style with shoulder - $8.00 each
(24 available)

Single FT243 Socket - smaller black type - single hole mount - $6.00 each
(4 available)

DUAL FT243 socket - square phenolic, Cinch, single hole mount, accepts two crystals - $10.00
(1 available)

QUAD in-line FT243 socket for multiple crystals, end to end on nice small copper subchassis - as used in DX100 - $24.00
(1 available)

HC6U Crystal Sockets - 1/2" spacing X 0.050" diameter pins
These are new ceramic sockets, single hole mount.
Available for $3.00 each or ten for $25.00 plus shipping
(60 available)

Triple hc6u socket - black or white - $5.00 each
(2 available)

Used hc6u sockets available for $2.00 each
(4 available)

CR1A (20C, DC30) crystal sockets, rare - pin spacing 0.5" and pin diameter 0.125" - for $4.00 each
(2 available)

DC34 / DC35 crystal sockets, Ceramic. rare - pin spacing 0.75" and pin diameter 0.125" - for
$4.00 each
(14 available)

DC34 / DC35 crystal sockets, Plastic. Rare - pin spacing 0.75" and pin diameter 0.125" - for
$4.00 each
(24 available)

CR-15/U Crystal socket, 3 pins New, Rare - 1-5/8" X 1-3/16" X 2" tall.
3 pins are 1/8" dia. Two are spaced 1/2" apart. third pin
is offset by 7/8" from each othe other two. $8.00 each
(2 available)

hc25 / hc50 crystal sockets, for the smaller metal can crystals, pc mount or attach wires
$2.50 each.
(5 available)

6242. Re: R-4A RCVR SENS adjust problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-19 20:01:00 UTC
From: Gary
Topic: 6211 Message: 6242

Well...
The first attempt was NOT good..

I bought 3 supposedly new 6BZ6's.
Did the filament wiring change (Thanks Garey, just like you
described.. it was nice of Drake to put in that terminal strip!!)

They all DID fix my RCVR SENS adjust problem. -1.35V, no problem.

BUT... Gain on these is REALLY bad. Calibrator S meter readings
changed from (gassy 12BZ6) S9+30 at 3.5MHz down to S9+5 (6BZ6).
ON 28.5MHz it went down from S6.5 to audible but NO S meter
deflection. Two of the 6BZ6s were pretty identical, the third was
slightly worse.
Is there any way that I need to change the biasing or something?

Oh, this was after tweeking all the input trimmers.

Also, I checked the SLOW cap, adjusted to -1.36V on SLOW, if I
switch to FAST, it goes down to -1.28V, not too bad? (with non-gassy
6BZ6)

SO.. for now I am back to my old original(?) 12BZ6, it does work
really well. Now, since it is bleeding off AVC voltage, that does
make it have more gain... what is the downside?

Easier to overload? Never had a signal too big so far...

S meter is reading wrong? Not too worried about that...

SLOW time constant is slightly faster. This might be the worst
problem, but it still is slower than my TS-440S.

Thanks for the advise,
73,
Gary WB6OGD

FOR SALE: ELECTROLYTIC CAPACITORS

Mix of radial, axial, upright can - some NOS. Almost all are new.
(one or two may be good, tested caps)

BOX #1 = QTY 35 electrolytic CAPACITORS
QTY 2, 0.068 uF at 630 V
QTY 2, 0.056 uF at 630 V
QTY 1, 4 uF at 600 V
QTY 2, 8 uF at 450 V
QTY 1, 8 + 8 uF at 450 V
QTY 2, 16 uF at 450 V
QTY 1, 125 uF at 450 V
QTY 1, 10 + 10 uF at 450 V
QTY 2, 820 uF at 450 V
QTY 1, 40 uF at 450 V
QTY 1, 68 uF at 400 V
QTY 4, 220 uF at 400V
QTY 2, 33 uF at 400V
QTY 1, 40 + 20 + 10 uF at 350 V
QTY 1, 22 uF at 350 V
QTY 1, 10 uF at 350 V
QTY 1, 100 uF at 250 V
QTY 1, 100 uF at 200 V
QTY 1, 4700 uF at 35 V
QTY 1, 4.7 uF at 35 V
QTY 2, 2200 uF at 25 V
QTY 4, 100 uF at 25 V
Total of 35 excellent capacitors for $45.00 plus $12.00 shipping

BOX #2 = QTY 40 electrolytic CAPACITORS
Mix of radial, axial, upright can - some NOS. Almost all are new.
QTY 2, 0.068 uF at 630 V
QTY 2, 0.056 uF at 630 V
QTY 1, 16 uF at 600V
QTY 1, 0.47 uF at 600V
QTY 2, 47 uF at 450 V
QTY 1, 20 uF at 450 V
QTY 1, 10 + 10 uF at 450 V
QTY 3, 82 uF at 400 V
QTY 5, 220 uF at 400 V
QTY 1, 33 uF at 400 V
QTY 3, 0.47 uF at 400 V

6245. T4XC Problem

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-21 13:35:58 UTC
From: Richard Hanna
Topic: 6245 Message: 6245

My T4XC is giving me fits! Basic problem is no plate current when I put the Mode Switch in "Tune" or key the mike in SSB. What makes it worse is intermittently I get plate current and when I tune the drive it goes away completely.

My checking indicates there is continuity from the bottom of the 3.3 ohm resistor to the cathodes of the finals, but when I power the rig up (mode switch in TUNE) there is no voltage from the cathodes to ground. (Manual says .8 volts). I think this confirms no current flow! Further on the schematic it looks like the bottom end of the resistor goes to the mode switch and back through the relay mute contact on transmit. I tried another relay and problem is still there. Leaves me with the thought that I have a mode switch problem.

Did try a little Deoxit on the mode switch to no avail. It looks like the terminal on the relay PC board has white-black wires, and I think I found one on the MODE switch, but no continuity on that connection. Afraid to try putting a jumper in because I'm not sure I have the right wire.

Any ideas on what to try further..

Thanks for any help or thought! Happy Holidays to the group!

Dick Hanna

6246. TR7 1st and second Mixer's

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-21 17:15:14 UTC
From: Keith Evans
Topic: 6246 Message: 6246

Hi All,

I wonder if anyone has done these mods ??

I understand replacing the 1st mixer with a SRA3MH+ is good for about another 1.7 DB off the Noise Floor.
I have also seen the TAK 3H mentioned, So comments please, as this maybe a better choice as it is more modern.

re the 2nd Mixer, I Understand that swopping out the 4148's and replacing with either matched
1N5711's or the HP Diodes Hot Carrier Diodes. is also worthwhile.
My TR7 is a fairly late model, with the 4 Diode / 4 resistor second Mixer, as opposed to the earlier
8 diode, no resistor configeration.
I think the earlier board did have a higher conversion loss, because of the extra diodes, although a
" Stronger " design, But it was changed by Drake, to try to find more sensitivity.
So I guess the Mod requires the Resistors to remain, and just change out the 4 Diodes.

I see Pete KE9OA in an Old Post recommends these Mods, Which has got me thinking,
but I wonder if others have done them, as increasing the sensitivity, without adding a Pre-Amp,
in front of the 1st Mixer would be benificial.

Seasons Greetings

73 Keith G3VKW

From: Richard Hanna
Topic: 6245 Message: 6247

OK..my bad....I was using a spare AC-4 and had not set the bias. Problem appears to be drive. When adjusting drive I see a very slight peak, but only to a max of about 110ma.

Does anyone have an RF voltage chart for the T4XC? I did do the checks for the oscillators working. and the PTO will drive the R4C.

Also tried substituting the 12BY7 driver, and the 6AU6 mixer.

Dick

I put Schottky diodes in the 2nd mixer of my TR-7, and had a slight but measurable increase in MDS. Another one I tried it with didn't show the same improvement. YMMV.

Hi Garey,

Checked R44, measures 700 ohms. Diode checks OK. Voltage checks on V4 are per the book.

Hi
Just a one off. Had similar problem. Have you checked the 100R 5w resistor in the AC-4?

Cheers and best wishes to all for the holidays.

Hi Jim,
Thanks for that info.
I modded my original TR7 back in the late 80's with HP Diodes, it was the original 8 diode setup, and I found,
minimal differance on that radio. Perhaps I should have swopped it to the 4 diode / 4 resistor setup.

re The 1st Mixer, I see that DK4DDS has a Circuit on his website of a design, That seems to match the Ports
in a much better (far more complex) way than the original, and that uses a SAY-1 Mixer.
This maybe from the article that was in the German magazine refered to a week or so back.
Is the same guy who had the ARRL Article when he had a PA0 call

Seasons greetings

I modded one for a friend that had the 8-diode setup, which I changed to diode/resistor. That may have been the one that I noted minimal improvement on, I'd have to see if I have info in my notes on it. I used Schottky diodes that I purchased in bulk on tape-and-reel packaging from a UK ePay seller, and curdely hand-sorted them for matching with my Fluke VOM. At any rate, it didn't seem to hurt the preformance any, so I left them in.

I've seen his articles, that's a pretty radical rebuild. I find some of it interesting, but I think that some things could be done just as well, or better, with modern outboard accessories. I disagree with his comments about the PA deck, the Drake design is about as bulletproof as I have ever seen without fancy protection methods and seems quite reliable. The predriver seems a bit problematic, especially the early version, but that's another story. The PIN diode attenuator looks to (IMO) be a lot of trouble to solve something that is a non-problem for most people, and a better method might be to re-engineer the negative feedback in the predriver and PA circuits for better gain flatness across the spectrum. Particularly in the predriver; I may revisit that at some point, as I'm not completely happy with my fix for the 40 Meter oscillation problem, and I think that the feedback networks could be further improved. I probably should learn how to model those circuits in software ... maybe I'll have time after I retire. :)

I note also that he comments about reversing the direction of the fan; I have previously debunked this notion as being less than desirable and published the info on the internet (QST subsequently picked it up also). It is one good way to increase drift across T/R cycles. It seems to me that using a thermostatically controlled fan may also contribute to increased drift, but I don't currently have much interest in empirically testing this. Maybe somone else can try it. I'm not opposed to technically sound mods, but even something as simple as saying "reverse the fan" should be tested to see how it affects the "big picture" before it becomes universally accepted.

Hi again Jim,

Yes I am with you, re your comments.

The VFO stabilising circuit maybe a reasonable addition, I see a UK company produces a smaller more modern version, but their out of stock, but a new version should be available Dec !!!
I think that was added by an SM station to his TR7 I saw on the i/net

My 1st TR7 had the earlier driver, which failed after about 18 month's, The Drake agent in the UK
Fixed it, and later I purchased an upgrade kit with the later ver2 PCB.
I have not suffered the Thermal runaway issue with the ver2 board, on either the upgraded TR7 or the much later one, but sometime when I next have the covers off I may add the resistors to it.

It was the Thread I read from KE9OA, that got me thinking re the 2 mixer mods as I figuerd to get
that much better Noise Floor, with such little effort, was quite a bonus.

Hi Keith,

On Fri, 23 Dec 2011 17:28:25 -0000, Keith Evans wrote:

>The VFO stabilising circuit maybe a reasonable addition

To each their own. I find my TR-7 to be quite stable enough after warm-up. But then, my first SW receiver was an S-120, my first HF rig an HW-101, so that tells you where I come from.

>I have not suffered the Thermal runaway issue with the ver2 board, on either the upgraded TR7 or the much later one, but sometime when I next have the covers off I may add the resistors to it.

I installed the resistor mod when I reworked my entire PA deck a week prior to Field Day a few years back (details in the Drakelist online forum). My predriver output transistor seemed to be a little "tired", although it still had output, so I replaced it with a more modern device for the high frequency gain benefit. Heat production did seem a bit less with the resistors, so I can't say that it hurt anything. They could always be bypassed at RF also, to get back to about the same point as before from an AC standpoint while keeping the DC runaway protection. Whatever. :)

>It was the Thread I read from KE9OA, that got me thinking re the 2 mixer mods as I figuerd to get
>that much better Noise Floor, with such little effort, was quite a bonus.

I'm looking at under a quarter of a microvolt MDS on my TR-7, as I recall, and it doesn't get much better than that for HF. I would be interested in the amount of improvement that some of these other mods display, but I have a hunch that much of it won't be worth the effort 99% of the time. I'm looking into noise in the RX audio chain at the moment. The 2N3904 is a good generic workhorse, but is not an exceptionally quiet device. I have some BC549B on order that have better noise figure specs, and will be changing out 3904s to see what difference it makes. An audio guru I work with also recommended LOTS of filter capacitance on the power rail to the audio PA chip, that's easy enough. I saw a note some years ago from a ham who added a low-pass R/C filter in the audio chain to reduce the bandwidth for better CW copy. I corresponded with him about changing the filter values for SSB operation to cut some of the high frequency hiss, but he didn't have the info any more that he used on the circuit impedances and didn't seem to be interested in going down that road. At the time, I was into Mode A satellites with 10-meter downlinks (IOW, weak-signal work), and the HF hiss was quite annoying in the headphones. I ended up parking a RadShack DSP-40 inline, an effective enough fix.

6256. Drake R4B and SPR-4

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-23 19:08:45 UTC
From: David Rogers
Topic: 6162 Message: 6256

The specs on the filters and noise blanker in these two radios look very similar. Other than the passband tuning and the fact that the SPR-4 is fully solid state, are these radios essentially similar, performance-wise?

David, WA7ZYQ

David,
With all due respect to others' feelings, it IS an apples and oranges question. The R4B in my mind is THE best receiver Drake ever made until maybe the R7/R8 series. It is not just ham bands only either, with the addition of optional band crystals, it is an EXCELLENT general coverage receiver. 4kc is a bit narrow for international broadcast, unfortunately, the only downside in my mind, and I don't know if the SPR-4 is better in that regard. That might make it a better choice for "general" listening.

I agree with Don in that the R4b is a great receiver but crystals are expensive and hard to come by. An FS4 is a nice addition but that adds $300 to the price tag IF you can find one. The SPR4 goes for about 350 and is plug n play. It stays cooler because it's solid state and the chassis doesn't oxidize like the R4b.

If you don't plan to use it with a transmitter and you're looking for something that receives sw and ham bands I think the SPR4 is a more suitable choice. If you want to add a tx later you will need the FA4 interface. With all due respect :-)

Oh! The filtering in the R4B is the LC type while the SPR 4 has a crystal filter with minimal ringing albeit much wider. The NB in the SPR4 is superior to that of the R4b especially for pulsating noise. But IMHO nothing beats a late serial numbered Sherwood modified R4C with all the filters and an aligned NB4.

From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 6264

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

6265. Faulty TR-7, I have nearly tried everything!

G'day all.

I have an early TR-7, I do not know its history and it arrived dead.

The series pass transistor on the PSU board (the one with flying leads to chassis) was shorted, a replacement just arrived today from the USA.

Put it in, the radio has audio hiss, but no rx, no digital display, but the passband tune does alter the audio hiss pitch.

I noticed after a minute or so the right side of the chassis (where the pass transistor is mounted) was getting very hot, it was drawing nearly 4 amps !, I would say something somewhere is shorted out and causing the abnormal current drain, so I started pulling bits out.

I have got to the stage of pulling EVERY plug in board out, dial lamps, disconnected the V+ line to the ALC board (as its not unpluggable), disconnected the PA/Driver stage but still drawing a bit over 2 amps which I'd say is way too much.

Has anyone had this problem before? I'd really like to get this TR7 working. Or any ideas ? About the only sections Ive not removed are the low pass/ high pass units as they look quite complex to pull out, I have not attempted to remove the PTO either.

Thanks. Ross VK3BRN

Hi Ross,

Do you have the Service manual??
If not you can download it I think off the Internet A big file though.

The PA supply is seperate from the rest of the Rig. It is on a different Pin on the 4 way socket.

I would check the power regulator board 1st to make sure that is giving the regulated 10 Volts, and that no Tantalum Caps in that area have gone short.

FWIW

G'day Keith.....Yes I have a full service manual and extender boards. Since my last post (Ive been working on it the whole time) I found a shorted tantalum on the 5V rail on the underside of the motherboard. What happened was I assumed (bad move!) that because I could see 5V around the logic sections it was ok, then I noticed there is a 5v rail straight off the psu board which is just tapped off the 10V rail. I removed a wire from the underside of the PSU board (the 5V line) and no change..finally (with a big magnifier) I noticed there were 2 wires coming off this 5V tap...followed it through and first thing it came to was a couple of tantalums....and that was it!!!
Still has faults though.....

1. The last 2-3 digits of the display are jumping around, but it is not moving in frequency.

2. The RX is normal but the audio qlty is very poor...it sounds like a chainsaw running in the background all the time....it gets even worse when the CAL button is pushed in. Its so bad its unusable at the moment but signals are very strong and the sensitivity seems ok., Ive not tested the TX Audio but its putting out full output

I have another good working TR7 but would really like to get this one running without doing "board swaps"

Hi Ross,
I had a problem recently with my TR7 which had same symptoms as yours. That pass transistor got so hot in 3 or 4 seconds It would almost burn skin off finger when touched.
Same other symptoms as yours too.

Turned out I had plugged the translator board in to the molex pin header mounted on parent board wrong. It felt good when going in, sort of a sliding friction feel, but when looking at marks left by translator board on side of shield I could see it was not quite vertical. The pins from parent board molex were slid in up against foil on PCB of translator, rather than where they should have been, inside female molex header and some were shorting to ground. Drove me nuts till I asked here and got a tip about this!

Shorting those pins to gnd also opened up a transistor junction on the transmit exciter board. The transistor was doing what it should...acting like a fuse. I had no Rx audio, or AGC...S meter would not move when RF gain was full CCW.
It was a 2N3904 that shorted on the 10v reg DC line, I think it was Q308. Since you still have Rx audio hiss, yours is probably OK though. The 10v reg line for Rx is what died on mine after my shorting those translator board pins enough times and I had no audio at all eventually. Q308 acts as a switch to give 10v reg on for when TR7 is in Rx.

The sequence of posts about it are in here if you do a search.
Good luck!
My TR7 has been in daily use since with no troubles.
It was an easy thing to have happened, hard to see down in there where it plugs in.!

Well done Ross,
re the digits jumping around, have you tried the switch to Freq Counter, and does it still do it??
it maybe corrosion on some of the Plugs and sockets of the DR7, but only guessing,
as I haven't had that problem.
re the Chainsaw, that maybe another Tantelum around the Audio Out Chip.

Replace the electrolytic filter capacitor in the DC-DC converter that provides the +24v supply on the PS board. These can cause strange problems when they go bad, and should be replaced anyway as a part of maintenance even if not the source of your problem. It's time. Also look at any electrolytics on the DR-7.

I see you got that 10 reg solved, great!
Time lag here as I chose to get daily emails from group.

Have a great new year all.

6272. Daiwa RF-440 speech processor manual

Yahoo group: DrakeRadio (2006 — 2011)
Date: 2011-12-31 22:36:05 UTC
From: stephen
Topic: 6272 Message: 6272

Hi group,

I am looking for the users manual and/or schematic for the external speech processor termed Daiwa RF-440, which was often used on Drake and other rigs of this vintage. One guy offers to sell you the PDF on ebay, but, there must be a better way for hams to share information.
